What is the AWS Encryption SDK?

The AWS Encryption SDK is a client-side encryption library designed to make it easy for everyone to encrypt and decrypt data using industry standards and best practices. It enables you to focus on the core functionality of your application, rather than on how to best encrypt and decrypt your data. The AWS Encryption SDK is provided free of charge under the Apache 2.0 license.

The AWS Encryption SDK answers questions like the following for you:

- Which encryption algorithm should I use?
- How, or in which mode, should I use that algorithm?
- How do I generate the encryption key?
- How do I protect the encryption key, and where should I store it?
- How can I make my encrypted data portable?
- How do I ensure that the intended recipient can read my encrypted data?
- How can I ensure my encrypted data is not modified between the time it is written and when it is read?
- How do I use the data keys that AWS KMS returns?

With the AWS Encryption SDK, you define a [master key provider \(p. 7\)](#) (Java and Python) or a [keyring \(p. 7\)](#) (C, C#/.NET, and JavaScript) that determines which wrapping keys you use to protect your data. Then you encrypt and decrypt your data using straightforward methods provided by the AWS Encryption SDK. The AWS Encryption SDK does the rest.

Without the AWS Encryption SDK, you might spend more effort on building an encryption solution than on the core functionality of your application. The AWS Encryption SDK answers these questions by providing the following things.

A default implementation that adheres to cryptography best practices

By default, the AWS Encryption SDK generates a unique data key for each data object that it encrypts. This follows the cryptography best practice of using unique data keys for each encryption operation.

The AWS Encryption SDK encrypts your data using a secure, authenticated, symmetric key algorithm. For more information, see [the section called “Supported algorithm suites” \(p. 13\)](#).

A framework for protecting data keys with wrapping keys

The AWS Encryption SDK protects the data keys that encrypt your data by encrypting them under one or more wrapping keys. By providing a framework to encrypt data keys with more than one wrapping key, the AWS Encryption SDK helps make your encrypted data portable.

For example, encrypt data under an AWS KMS key in AWS KMS and a key from your on-premises HSM. You can use either of the wrapping keys to decrypt the data, in case one is unavailable or the caller doesn't have permission to use both keys.

A formatted message that stores encrypted data keys with the encrypted data

The AWS Encryption SDK stores the encrypted data and encrypted data key together in an [encrypted message \(p. 8\)](#) that uses a defined data format. This means you don't need to keep

track of or protect the data keys that encrypt your data because the AWS Encryption SDK does it for you.

Some language implementations of the AWS Encryption SDK require an AWS SDK, but the AWS Encryption SDK doesn't require an AWS account and it doesn't depend on any AWS service. You need an AWS account only if you choose to use [AWS KMS keys](#) to protect your data.

Developed in open-source repositories

The AWS Encryption SDK is developed in open-source repositories on GitHub. You can use these repositories to view the code, read and submit issues, and find information that is specific to your language implementation.

- AWS Encryption SDK for C — [aws-encryption-sdk-c](#)
- AWS Encryption SDK for .NET — [aws-encryption-sdk-net](#) directory of the `aws-encryption-sdk-dafny` repository.
- AWS Encryption CLI — [aws-encryption-sdk-cli](#)
- AWS Encryption SDK for Java — [aws-encryption-sdk-java](#)
- AWS Encryption SDK for JavaScript — [aws-encryption-sdk-javascript](#)
- AWS Encryption SDK for Python — [aws-encryption-sdk-python](#)

Compatibility with encryption libraries and services

The AWS Encryption SDK is supported in several [programming languages](#) (p. 68). All language implementations are interoperable. You can encrypt with one language implementation and decrypt with another. Interoperability might be subject to language constraints. If so, these constraints are described in the topic about the language implementation. Also, when encrypting and decrypting, you must use compatible keyrings, or master keys and master key providers. For details, see [the section called “Keyring compatibility”](#) (p. 47).

However, the AWS Encryption SDK cannot interoperate with other libraries. Because each library returns encrypted data in a different format, you cannot encrypt with one library and decrypt with another.

DynamoDB Encryption Client and Amazon S3 client-side encryption

The AWS Encryption SDK cannot decrypt data encrypted by the [DynamoDB Encryption Client](#) or [Amazon S3 client-side encryption](#). These libraries cannot decrypt the [encrypted message](#) (p. 8) the AWS Encryption SDK returns.

AWS Key Management Service (AWS KMS)

The AWS Encryption SDK can use [AWS KMS keys](#) and [data keys](#) to protect your data, including multi-Region KMS keys. For example, you can configure the AWS Encryption SDK to encrypt your data under one or more AWS KMS keys in your AWS account. However, you must use the AWS Encryption SDK to decrypt that data.

The AWS Encryption SDK cannot decrypt the ciphertext that the AWS KMS [Encrypt](#) or [ReEncrypt](#) operations return. Similarly, the AWS KMS [Decrypt](#) operation cannot decrypt the [encrypted message](#) (p. 8) the AWS Encryption SDK returns.

The AWS Encryption SDK supports only [symmetric encryption KMS keys](#). You cannot use an [asymmetric KMS key](#) for encryption or signing in the AWS Encryption SDK. The AWS Encryption SDK generates its own ECDSA signing keys for [algorithm suites \(p. 13\)](#) that sign messages.

For help deciding which library or service to use, see [How to Choose an Encryption Tool or Service](#) in *AWS Cryptographic Services and Tools*.

Support and maintenance

The AWS Encryption SDK uses the same [maintenance policy](#) that the AWS SDK and Tools use, including its versioning and life-cycle phases. As a [best practice \(p. 17\)](#), we recommend that you use the latest available version of the AWS Encryption SDK for your programming language, and upgrade as new versions are released. When a version requires significant changes, such as the upgrade from AWS Encryption SDK versions earlier than 1.7.x to versions 2.0.x and later, we provide [detailed instructions \(p. 200\)](#) to help you.

Each programming language implementation of the AWS Encryption SDK is developed in a separate open-source GitHub repository. The life-cycle and support phase of each version is likely to vary among repositories. For example, a given version of the AWS Encryption SDK might be in the general availability (full support) phase in one programming language, but the end-of-support phase in a different programming language. We recommend that you use a fully supported version whenever possible and avoid versions that are no longer supported.

To find the life-cycle phase of AWS Encryption SDK versions for your programming language, see the `SUPPORT_POLICY.rst` file in each AWS Encryption SDK repository.

- AWS Encryption SDK for C — [SUPPORT_POLICY.rst](#)
- AWS Encryption SDK for .NET — [SUPPORT_POLICY.rst](#)
- AWS Encryption CLI — [SUPPORT_POLICY.rst](#)
- AWS Encryption SDK for Java — [SUPPORT_POLICY.rst](#)
- AWS Encryption SDK for JavaScript — [SUPPORT_POLICY.rst](#)
- AWS Encryption SDK for Python — [SUPPORT_POLICY.rst](#)

For more information, see [Versions of the AWS Encryption SDK \(p. 194\)](#) and [AWS SDKs and Tools maintenance policy](#) in the AWS SDKs and Tools Reference Guide.

Learning more

For more information about the AWS Encryption SDK and client-side encryption, try these sources.

- For help with the terms and concepts used in this SDK, see [Concepts in the AWS Encryption SDK \(p. 4\)](#).
- For best practice guidelines, see [Best practices for the AWS Encryption SDK \(p. 17\)](#).
- For information about how this SDK works, see [How the SDK works \(p. 12\)](#).
- For examples that show how to configure options in the AWS Encryption SDK, see [Configuring the AWS Encryption SDK \(p. 20\)](#).
- For detailed technical information, see the [Reference \(p. 224\)](#).
- For the technical specification for the AWS Encryption SDK, see the [AWS Encryption SDK Specification](#) in GitHub.

- For answers to your questions about using the AWS Encryption SDK, read and post on the [AWS Crypto Tools Discussion Forum](#).

For information about implementations of the AWS Encryption SDK in different programming languages.

- **C:** See [AWS Encryption SDK for C \(p. 68\)](#), the [AWS Encryption SDK C documentation](#), and the [aws-encryption-sdk-c](#) repository on GitHub.
- **C#/.NET:** See [AWS Encryption SDK for .NET \(p. 77\)](#) and the [aws-encryption-sdk-net](#) directory of the [aws-encryption-sdk-dafny](#) repository on GitHub.
- **Command Line Interface:** See [AWS Encryption SDK command line interface \(p. 112\)](#), [Read the Docs](#) for the AWS Encryption CLI, and the [aws-encryption-sdk-cli](#) repository on GitHub.
- **Java:** See [AWS Encryption SDK for Java \(p. 85\)](#), the AWS Encryption SDK [Javadoc](#), and the [aws-encryption-sdk-java](#) repository on GitHub.

JavaScript: See [the section called "JavaScript" \(p. 95\)](#) and the [aws-encryption-sdk-javascript](#) repository on GitHub.

- **Python:** See [AWS Encryption SDK for Python \(p. 103\)](#), the AWS Encryption SDK [Python documentation](#), and the [aws-encryption-sdk-python](#) repository on GitHub.

Sending feedback

We welcome your feedback! If you have a question or comment, or an issue to report, please use the following resources.

- If you discover a potential security vulnerability in the AWS Encryption SDK, please [notify AWS security](#). Do not create a public GitHub issue.
- To provide feedback on the AWS Encryption SDK, file an issue in the GitHub repository for the programming language you are using.
- To provide feedback on this documentation, use the **Feedback** links on this page. You can also file an issue or contribute to [aws-encryption-sdk-docs](#), the open-source repository for this documentation on GitHub.

Concepts in the AWS Encryption SDK

This section introduces the concepts used in the AWS Encryption SDK, and provides a glossary and reference. It's designed to help you understand how the AWS Encryption SDK works and the terms we use to describe it.

Need help?

- Learn how the AWS Encryption SDK uses [envelope encryption \(p. 5\)](#) to protect your data.
- Learn about the elements of envelope encryption: the [data keys \(p. 6\)](#) that protect your data and the [wrapping keys \(p. 7\)](#) that protect your data keys.
- Learn about the [keyrings \(p. 7\)](#) and [master key providers \(p. 7\)](#) that determine which wrapping keys you use.
- Learn about the [encryption context \(p. 8\)](#) that adds integrity to your encryption process. It's optional, but it's a best practice that we recommend.
- Learn about the [encrypted message \(p. 8\)](#) that the encryption methods return.
- Then you're ready to use the AWS Encryption SDK in your preferred [programming language \(p. 68\)](#).

Topics

- [Algorithm suite](#) (p. 9)
- [Cryptographic materials manager](#) (p. 9)
- [Symmetric and asymmetric encryption](#) (p. 9)
- [Key commitment](#) (p. 10)
- [Commitment policy](#) (p. 11)
- [Digital signatures](#) (p. 12)

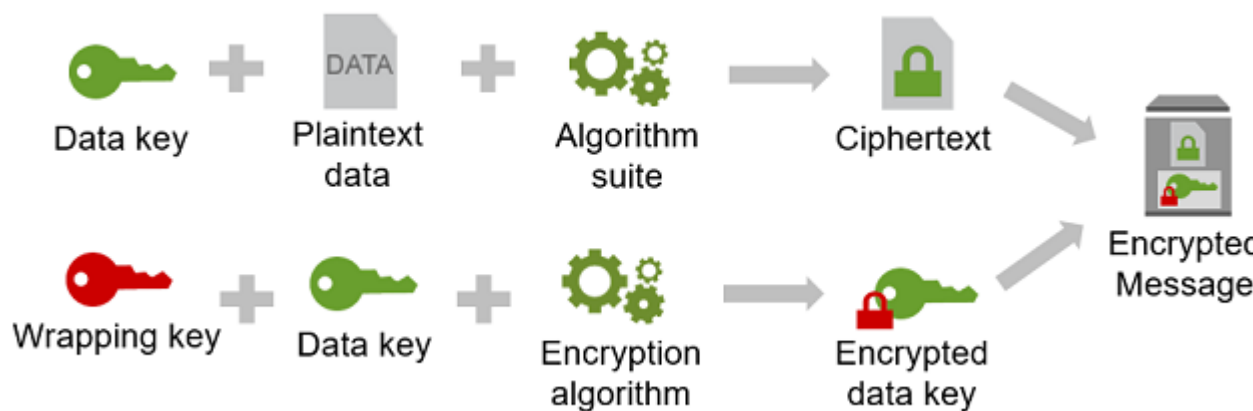

Envelope encryption

The security of your encrypted data depends in part on protecting the data key that can decrypt it. One accepted best practice for protecting the data key is to encrypt it. To do this, you need another encryption key, known as a *key-encryption key* or [wrapping key](#) (p. 7). The practice of using a wrapping key to encrypt data keys is known as *envelope encryption*.

Protecting data keys

The AWS Encryption SDK encrypts each message with a unique data key. Then it encrypts the data key under the wrapping key you specify. It stores the encrypted data key with the encrypted data in the encrypted message that it returns.

To specify your wrapping key, you use a [keyring](#) (p. 7) or [master key provider](#) (p. 7).

Encrypting the same data under multiple wrapping keys

You can encrypt the data key under multiple wrapping keys. You might want to provide different wrapping keys for different users, or wrapping keys of different types, or in different locations. Each of the wrapping keys encrypts the same data key. The AWS Encryption SDK stores all of the encrypted data keys with the encrypted data in the encrypted message.

To decrypt the data, you need to provide a wrapping key that can decrypt one of the encrypted data keys.

Combining the strengths of multiple algorithms

To encrypt your data, by default, the AWS Encryption SDK uses a sophisticated [algorithm suite \(p. 13\)](#) with AES-GCM symmetric encryption, a key derivation function (HKDF), and signing. To encrypt the data key, you can specify a [symmetric or asymmetric encryption algorithm \(p. 9\)](#) appropriate to your wrapping key.

In general, symmetric key encryption algorithms are faster and produce smaller ciphertexts than asymmetric or *public key encryption*. But public key algorithms provide inherent separation of roles and easier key management. To combine the strengths of each, you can encrypt your data with symmetric key encryption, and then encrypt the data key with public key encryption.

Data key

A *data key* is an encryption key that the AWS Encryption SDK uses to encrypt your data. Each data key is a byte array that conforms to the requirements for cryptographic keys. Unless you're using [data key caching \(p. 152\)](#), the AWS Encryption SDK uses a unique data key to encrypt each message.

You don't need to specify, generate, implement, extend, protect or use data keys. The AWS Encryption SDK does that work for you when you call the encrypt and decrypt operations.

To protect your data keys, the AWS Encryption SDK encrypts them under one or more *key-encryption keys* known as [wrapping keys \(p. 7\)](#) or master keys. After the AWS Encryption SDK uses your plaintext data keys to encrypt your data, it removes them from memory as soon as possible. Then it stores the encrypted data keys with the encrypted data in the [encrypted message \(p. 8\)](#) that the encrypt operations return. For details, see [the section called "How the SDK works" \(p. 12\)](#).

Tip

In the AWS Encryption SDK, we distinguish *data keys* from *data encryption keys*. Several of the supported [algorithm suites \(p. 9\)](#), including the default suite, use a [key derivation function](#) that prevents the data key from hitting its cryptographic limits. The key derivation function takes the data key as input and returns a data encryption key that is actually used to encrypt the data. For this reason, we often say that data is encrypted "under" a data key rather than "by" the data key.

Each encrypted data key includes metadata, including the identifier of the wrapping key that encrypted it. This metadata makes it easier for the AWS Encryption SDK to identify valid wrapping keys when decrypting.

Wrapping key

A *wrapping key* is a key-encryption key that the AWS Encryption SDK uses to encrypt the [data key \(p. 6\)](#) that encrypts your data. Each plaintext data key can be encrypted under one or more wrapping keys. You determine which wrapping keys are used to protect your data when you configure a [keyring \(p. 7\)](#) or [master key provider \(p. 7\)](#).

Note

Wrapping key refers to the keys in a keyring or master key provider. *Master key* is typically associated with the `MasterKey` class that you instantiate when you use a master key provider.

The AWS Encryption SDK supports several commonly used wrapping keys, such as AWS Key Management Service (AWS KMS) symmetric [AWS KMS keys](#) (including [multi-Region KMS keys \(p. 21\)](#)), raw AES-GCM (Advanced Encryption Standard/Galois Counter Mode) keys, and raw RSA keys. You can also extend or implement your own wrapping keys.

When you use envelope encryption, you need to protect your wrapping keys from unauthorized access. You can do this in any of the following ways:

- Use a web service designed for this purpose, such as [AWS Key Management Service \(AWS KMS\)](#).
- Use a [hardware security module \(HSM\)](#) such as those offered by [AWS CloudHSM](#).
- Use other key management tools and services.

If you don't have a key management system, we recommend AWS KMS. The AWS Encryption SDK integrates with AWS KMS to help you protect and use your wrapping keys. However, the AWS Encryption SDK does not require AWS or any AWS service.

Keyrings and master key providers

To specify the wrapping keys you use for encryption and decryption, you use a keyring (C, C# / .NET, and JavaScript) or a master key provider (Java, Python, CLI). You can use the keyrings and master key providers that the AWS Encryption SDK provides or design your own implementations. The AWS Encryption SDK provides keyrings and master key providers that are compatible with each other subject to language constraints. For details, see [Keyring compatibility \(p. 47\)](#).

A *keyring* generates, encrypts, and decrypts data keys. When you define a keyring, you can specify the [wrapping keys \(p. 7\)](#) that encrypt your data keys. Most keyrings specify at least one wrapping key or a service that provides and protects wrapping keys. You can also define a keyring with no wrapping keys or a more complex keyring with additional configuration options. For help choosing and using the keyrings that the AWS Encryption SDK defines, see [Using keyrings \(p. 45\)](#). Keyrings are supported in C, C# / .NET, and JavaScript.

A *master key provider* is an alternative to a keyring. The master key provider returns the wrapping keys (or master keys) you specify. Each master key is associated with one master key provider, but a master key provider typically provides multiple master keys. Master key providers are supported in Java, Python, and the AWS Encryption CLI.

You must specify a keyring (or master key provider) for encryption. You can specify the same keyring (or master key provider), or a different one, for decryption. When encrypting, the AWS Encryption SDK uses all of the wrapping keys you specify to encrypt the data key. When decrypting, the AWS Encryption SDK uses only the wrapping keys you specify to decrypt an encrypted data key. Specifying wrapping keys for decryption is optional, but it's a AWS Encryption SDK [best practice \(p. 17\)](#).

For details about specifying wrapping keys, see [Select wrapping keys \(p. 20\)](#).

Encryption context

To improve the security of your cryptographic operations, include an [encryption context](#) in all requests to encrypt data. Using an encryption context is optional, but it is a cryptographic best practice that we recommend.

An *encryption context* is a set of name-value pairs that contain arbitrary, non-secret additional authenticated data. The encryption context can contain any data you choose, but it typically consists of data that is useful in logging and tracking, such as data about the file type, purpose, or ownership. When you encrypt data, the encryption context is cryptographically bound to the encrypted data so that the same encryption context is required to decrypt the data. The AWS Encryption SDK includes the encryption context in plaintext in the header of the [encrypted message \(p. 8\)](#) that it returns.

The encryption context that the AWS Encryption SDK uses consists of the encryption context that you specify and a public key pair that the [cryptographic materials manager \(p. 9\)](#) (CMM) adds. Specifically, whenever you use an [encryption algorithm with signing \(p. 241\)](#), the CMM adds a name-value pair to the encryption context that consists of a reserved name, `aws-crypto-public-key`, and a value that represents the public verification key. The `aws-crypto-public-key` name in the encryption context is reserved by the AWS Encryption SDK and cannot be used as a name in any other pair in the encryption context. For details, see [AAD \(p. 226\)](#) in the *Message Format Reference*.

The following example encryption context consists of two encryption context pairs specified in the request and the public key pair that the CMM adds.

```
"Purpose"="Test", "Department"="IT", aws-crypto-public-key=<public key>
```

To decrypt the data, you pass in the encrypted message. Because the AWS Encryption SDK can extract the encryption context from the encrypted message header, you are not required to provide the encryption context separately. However, the encryption context can help you to confirm that you are decrypting the correct encrypted message.

- In the [AWS Encryption SDK Command Line Interface \(p. 112\)](#) (CLI), if you provide an encryption context in a decrypt command, the CLI verifies that the values are present in the encryption context of the encrypted message before it returns the plaintext data.
- In other programming language implementations, the decrypt response includes the encryption context and the plaintext data. The decrypt function in your application should always verify that the encryption context in the decrypt response includes the encryption context in the encrypt request (or a subset) before it returns the plaintext data.

When choosing an encryption context, remember that it is not a secret. The encryption context is displayed in plaintext in the header of the [encrypted message \(p. 8\)](#) that the AWS Encryption SDK returns. If you are using AWS Key Management Service, the encryption context also might appear in plaintext in audit records and logs, such as AWS CloudTrail.

For examples of submitting and verifying an encryption context in your code, see the examples for your preferred [programming language \(p. 68\)](#).

Encrypted message

When you encrypt data with the AWS Encryption SDK, it returns an encrypted message.

An *encrypted message* is a portable [formatted data structure \(p. 224\)](#) that includes the encrypted data along with encrypted copies of the data keys, the algorithm ID, and, optionally, an [encryption](#)

[context](#) (p. 8) and a [digital signature](#) (p. 12). Encrypt operations in the AWS Encryption SDK return an encrypted message and decrypt operations take an encrypted message as input.

Combining the encrypted data and its encrypted data keys streamlines the decryption operation and frees you from having to store and manage encrypted data keys independently of the data that they encrypt.

For technical information about the encrypted message, see [Encrypted Message Format](#) (p. 224).

Algorithm suite

The AWS Encryption SDK uses an algorithm suite to encrypt and sign the data in the [encrypted message](#) (p. 8) that the encrypt and decrypt operations return. The AWS Encryption SDK supports several [algorithm suites](#) (p. 13). All of the supported suites use Advanced Encryption Standard (AES) as the primary algorithm, and combine it with other algorithms and values.

The AWS Encryption SDK establishes a recommended algorithm suite as the default for all encryption operations. The default might change as standards and best practices improve. You can specify an alternate algorithm suite in requests to encrypt data or when creating a [cryptographic materials manager \(CMM\)](#) (p. 9), but unless an alternate is required for your situation, it is best to use the default. The current default is AES-GCM with an HMAC-based extract-and-expand [key derivation function \(HKDF\)](#), [key commitment](#) (p. 10), an [Elliptic Curve Digital Signature Algorithm \(ECDSA\)](#) (p. 12) signature, and a 256-bit encryption key.

If your application requires high performance and the users who are encrypting data and those who are decrypting data are equally trusted, you might consider specifying an algorithm suite without a digital signature. However, we strongly recommend an algorithm suite that includes key commitment and a key derivation function. Algorithm suites without these features are supported only for backward compatibility.

Cryptographic materials manager

The cryptographic materials manager (CMM) assembles the cryptographic materials that are used to encrypt and decrypt data. The *cryptographic materials* include plaintext and encrypted data keys, and an optional message signing key. You never interact with the CMM directly. The encryption and decryption methods handle it for you.

You can use the default CMM or the [caching CMM](#) (p. 152) that the AWS Encryption SDK provides, or write a custom CMM. And you can specify a CMM, but it's not required. When you specify a keyring or master key provider, the AWS Encryption SDK creates a default CMM for you. The default CMM gets the encryption or decryption materials from the keyring or master key provider that you specify. This might involve a call to a cryptographic service, such as [AWS Key Management Service](#) (AWS KMS).

Because the CMM acts as a liaison between the AWS Encryption SDK and a keyring (or master key provider), it is an ideal point for customization and extension, such as support for policy enforcement and caching. The AWS Encryption SDK provides a caching CMM to support [data key caching](#). (p. 152)

Symmetric and asymmetric encryption

Symmetric encryption uses the same key to encrypt and decrypt data.

Asymmetric encryption uses a mathematically related data key pair. One key in the pair encrypts the data; only the other key in the pair can decrypt the data. For details, see [Cryptographic algorithms](#) in the *AWS Cryptographic Services and Tools Guide*.

The AWS Encryption SDK uses [envelope encryption](#) (p. 5). It encrypts your data with a symmetric data key. It encrypts the symmetric data key with one or more symmetric or asymmetric wrapping keys.

It returns an [encrypted message \(p. 8\)](#) that includes the encrypted data and at least one encrypted copy of the data key.

Encrypting your data (symmetric encryption)

To encrypt your data, the AWS Encryption SDK uses a symmetric [data key \(p. 6\)](#) and an [algorithm suite \(p. 9\)](#) that includes a symmetric encryption algorithm. To decrypt the data, the AWS Encryption SDK uses the same data key and the same algorithm suite.

Encrypting your data key (symmetric or asymmetric encryption)

The [keyring \(p. 7\)](#) or [master key provider \(p. 7\)](#) that you supply to an encrypt and decrypt operation determines how the symmetric data key is encrypted and decrypted. You can choose a keyring or master key provider that uses symmetric encryption, such as a AWS KMS keyring, or one that uses asymmetric encryption, such as a raw RSA keyring or `JceMasterKey`.

Key commitment

The AWS Encryption SDK supports *key commitment* (sometimes known as *robustness*), a security property that guarantees that each ciphertext can be decrypted only to a single plaintext. To do this, key commitment guarantees that only the data key that encrypted your message will be used to decrypt it. Encrypting and decrypting with key commitment is an [AWS Encryption SDK best practice \(p. 17\)](#).

Most modern symmetric ciphers (including AES) encrypt a plaintext under a single secret key, such as the [unique data key \(p. 6\)](#) that the AWS Encryption SDK uses to encrypt each plaintext message. Decrypting this data with the same data key returns a plaintext that is identical to the original. Decrypting with a different key will usually fail. However, it's possible to decrypt a ciphertext under two different keys. In rare cases, it is feasible to find a key that can decrypt a few bytes of ciphertext into a different, but still intelligible, plaintext.

The AWS Encryption SDK always encrypts each plaintext message under one unique data key. It might encrypt that data key under multiple wrapping keys (or master keys), but the wrapping keys always encrypt the same data key. Nonetheless, a sophisticated, manually crafted [encrypted message \(p. 8\)](#) might actually contain different data keys, each encrypted by a different wrapping key. For example, if one user decrypts the encrypted message it returns 0x0 (false) while another user decrypting the same encrypted message gets 0x1 (true).

To prevent this scenario, the AWS Encryption SDK supports key commitment when encrypting and decrypting. When the AWS Encryption SDK encrypts a message with key commitment, it cryptographically binds the unique data key that produced the ciphertext to the *key commitment string*, a non-secret data key identifier. Then it stores key commitment string in the metadata of the encrypted message. When it decrypts a message with key commitment, the AWS Encryption SDK verifies that the data key is the one and only key for that encrypted message. If data key verification fails, the decrypt operation fails.

Support for key commitment is introduced in version 1.7.x, which can decrypt messages with key commitment, but won't encrypt with key commitment. You can use this version to fully deploy the ability to decrypt ciphertext with key commitment. Version 2.0.x includes full support for key commitment. By default, it encrypts and decrypts only with key commitment. This is an ideal configuration for applications that don't need to decrypt ciphertext encrypted by earlier versions of the AWS Encryption SDK.

Although encrypting and decrypting with key commitment is a best practice, we let you decide when it's used, and let you adjust the pace at which you adopt it. Beginning in version 1.7.x, AWS Encryption SDK supports a [commitment policy \(p. 11\)](#) that sets the [default algorithm suite \(p. 13\)](#) and limits the algorithm suites that may be used. This policy determines whether your data is encrypted and decrypted with key commitment.

Key commitment results in a [slightly larger \(+ 30 bytes\) encrypted message \(p. 224\)](#) and takes more time to process. If your application is very sensitive to size or performance, you might choose to opt out of key commitment. But do so only if you must.

For more information about migrating to versions 1.7.x and 2.0.x, including their key commitment features, see [Migrating to versions 2.0.x and later \(p. 200\)](#). For technical information about key commitment, see [the section called "Algorithms reference" \(p. 241\)](#) and [the section called "Message format reference" \(p. 224\)](#).

Commitment policy

A *commitment policy* is a configuration setting that determines whether your application encrypts and decrypts with [key commitment \(p. 10\)](#). Encrypting and decrypting with key commitment is an [AWS Encryption SDK best practice \(p. 17\)](#).

Commitment policy has three values.

Note

You might have to scroll horizontally or vertically to see the entire table.

Commitment policy values

Value	Encrypts with key commitment	Encrypts without key commitment	Decrypts with key commitment	Decrypts without key commitment
ForbidEncryptAllowDecrypt				
RequireEncryptAllowDecrypt				
RequireEncryptRequireDecrypt				

The commitment policy setting is introduced in AWS Encryption SDK version 1.7.x. It's valid in all supported [programming languages \(p. 68\)](#).

- `ForbidEncryptAllowDecrypt` decrypts with or without key commitment, but it won't encrypt with key commitment. This is the only valid value for commitment policy in version 1.7.x and it is used for all encrypt and decrypt operations. It's designed to prepare all hosts running your application to decrypt with key commitment before they ever encounter a ciphertext encrypted with key commitment.
- `RequireEncryptAllowDecrypt` always encrypts with key commitment. It can decrypt with or without key commitment. This value, introduced in version 2.0.x, lets you start encrypting with key commitment, but still decrypt legacy ciphertexts without key commitment.
- `RequireEncryptRequireDecrypt` encrypts and decrypts only with key commitment. This value is the default for version 2.0.x. Use this value when you are certain that all of your ciphertexts are encrypted with key commitment.

The commitment policy setting determines which algorithm suites you can use. Beginning in version 1.7.x, the AWS Encryption SDK supports [algorithm suites \(p. 13\)](#) for key commitment; with and without signing. If you specify an algorithm suite that conflicts with your commitment policy, the AWS Encryption SDK returns an error.

For help setting your commitment policy, see [Setting your commitment policy \(p. 211\)](#).

Digital signatures

To ensure the integrity of a digital message as it goes between systems, you can apply a digital signature to the message. Digital signatures are always asymmetric. You use your private key to create the signature, and append it to the original message. Your recipient uses a public key to verify that the message has not been modified since you signed it.

The AWS Encryption SDK encrypts your data using an authenticated encryption algorithm, AES-GCM, and the decryption process verifies the integrity and authenticity of an encrypted message without using a digital signature. But because AES-GCM uses symmetric keys, anyone who can decrypt the data key used to decrypt the ciphertext could also manually create a new encrypted ciphertext, causing a potential security concern. For instance, if you use an AWS KMS key as a wrapping key, this means that it is possible for a user with KMS Decrypt permissions to create encrypted ciphertexts without calling KMS Encrypt.

To avoid this issue, the AWS Encryption SDK supports adding an Elliptic Curve Digital Signature Algorithm (ECDSA) signature to the end of encrypted messages. When a signing algorithm suite is used, the AWS Encryption SDK generates a temporary private key and public key pair for each encrypted message. The AWS Encryption SDK stores the public key in the encryption context of the data key and discards the private key, and no one can create another signature that verifies with the public key. Because the algorithm binds the public key to the encrypted data key as additional authenticated data in the message header, a user who can only decrypt messages cannot alter the public key.

Signature verification adds a significant performance cost on decryption. If the users encrypting data and the users decrypting data are equally trusted, consider using an algorithm suite that does not include signing.

How the AWS Encryption SDK works

The workflows in this section explain how the AWS Encryption SDK encrypts data and decrypts [encrypted messages \(p. 8\)](#). These workflows describes the basic process using the default features. For details about defining and using custom components, see the GitHub repository for each supported [language implementation \(p. 68\)](#).

The AWS Encryption SDK uses envelope encryption to protect your data. Each message is encrypted under a unique data key. Then the data key is encrypted by the wrapping keys you specify. To decrypt the encrypted message, the AWS Encryption SDK uses the wrapping keys you specify to decrypt at least one encrypted data key. Then it can decrypt the ciphertext and return a plaintext message.

Need help with the terminology we use in the AWS Encryption SDK? See [the section called "Concepts" \(p. 4\)](#).

How the AWS Encryption SDK encrypts data

The AWS Encryption SDK provides methods that encrypt strings, byte arrays, and byte streams. For code examples, see the Examples topic in each [Programming languages \(p. 68\)](#) section.

1. Create a [keyring \(p. 45\)](#) (or [master key provider \(p. 7\)](#)) that specifies the wrapping keys that protect your data.

2. Pass the keyring and plaintext data to an encryption method. We recommend that you pass in an optional, non-secret [encryption context](#) (p. 8).
3. The encryption method asks the keyring for encryption materials. The keyring returns unique data encryption keys for the message: one plaintext data key and one copy of that data key encrypted by the each of the specified wrapping keys.
4. The encryption method uses the plaintext data key to encrypt the data, and then discards the plaintext data key. If you provide an encryption context (an AWS Encryption SDK [best practice](#) (p. 17)), the encryption method cryptographically binds the encryption context to the encrypted data.
5. The encryption method returns an [encrypted message](#) (p. 8) that contains the encrypted data, the encrypted data keys, and other metadata, including the encryption context, if you used one.

How the AWS Encryption SDK decrypts an encrypted message

The AWS Encryption SDK provides methods that decrypt the [encrypted message](#) (p. 8) and return plaintext. For code examples, see the Examples topic in each [Programming languages](#) (p. 68) section.

The [keyring](#) (p. 45) (or [master key provider](#) (p. 7)) that decrypts the encrypted message must be compatible with the one used to encrypt the message. One of its wrapping keys must be able to decrypt an encrypted data key in the encrypted message. For information about compatibility with keyrings and master key providers, see [the section called “Keyring compatibility”](#) (p. 47).

1. Create a keyring or master key provider with wrapping keys that can decrypt your data. You can use the same keyring that you provided to the encryption method or a different one.
2. Pass the [encrypted message](#) (p. 8) and the keyring to a decryption method.
3. The decryption method asks the keyring or master key provider to decrypt one of the encrypted data keys in the encrypted message. It passes in information from the encrypted message, including the encrypted data keys.
4. The keyring uses its wrapping keys to decrypt one of the encrypted data keys. If it's successful, the response includes the plaintext data key. If none of the wrapping keys specified by the keyring or master key provider can decrypt an encrypted data key, the decrypt call fails.
5. The decryption method uses the plaintext data key to decrypt the data, discards the plaintext data key, and returns the plaintext data.

Supported algorithm suites in the AWS Encryption SDK

An *algorithm suite* is a collection of cryptographic algorithms and related values. Cryptographic systems use the algorithm implementation to generate the ciphertext message.

The AWS Encryption SDK algorithm suite uses the Advanced Encryption Standard (AES) algorithm in Galois/Counter Mode (GCM), known as AES-GCM, to encrypt raw data. The AWS Encryption SDK supports 256-bit, 192-bit, and 128-bit encryption keys. The length of the initialization vector (IV) is always 12 bytes. The length of the authentication tag is always 16 bytes.

By default, the AWS Encryption SDK uses an algorithm suite with AES-GCM with an HMAC-based extract-and-expand key derivation function ([HKDF](#)), signing, and a 256-bit encryption key. If the [commitment policy](#) (p. 11) requires [key commitment](#) (p. 10), the AWS Encryption SDK selects an algorithm suite that also supports key commitment; otherwise, it selects an algorithm suite with key derivation and signing, but not key commitment.

Recommended: AES-GCM with key derivation, signing, and key commitment

The AWS Encryption SDK recommends an algorithm suite that derives an AES-GCM encryption key by supplying a 256-bit data encryption key to the HMAC-based extract-and-expand key derivation function (HKDF). The AWS Encryption SDK adds an Elliptic Curve Digital Signature Algorithm (ECDSA) signature. To support [key commitment](#) (p. 10), this algorithm suite also derives a *key commitment string* – a non-secret data-key identifier – that is stored in the metadata of the encrypted message. This key commitment string is also derived through HKDF using a procedure similar to deriving the data encryption key.

AWS Encryption SDK Algorithm Suite

Encryption algorithm	Data encryption key length (in bits)	Key derivation algorithm	Signature algorithm	Key commitment
AES-GCM	256	HKDF with SHA-384	ECDSA with P-384 and SHA-384	HKDF with SHA-512

The HKDF helps you avoid accidental reuse of a data encryption key and reduces the risk of overusing a data key.

For signing, this algorithm suite uses ECDSA with a cryptographic hash function algorithm (SHA-384). ECDSA is used by default, even when it is not specified by the policy for the underlying master key. [Message signing](#) (p. 12) verifies the message sender was authorized to encrypt messages and provides non-repudiation. It is particularly useful when the authorization policy for a master key allows one set of users to encrypt data and a different set of users to decrypt data.

Algorithm suites with key commitment ensure that each ciphertext decrypts to only one plaintext. They do this by validating the identity of the data key used as input to the encryption algorithm. When encrypting, these algorithm suites derive a key commitment string. Before decrypting, they validate that the data key matches the key commitment string. If it does not, the decrypt call fails.

Other supported algorithm suites

The AWS Encryption SDK supports the following alternate algorithm suites for backward compatibility. In general, we do not recommend these algorithm suites. However, we recognize that signing can hinder performance significantly, so we offer a key committing suite with key derivation for those cases. For applications that must make more significant performance tradeoffs, we continue to offer suites that lack signing, key commitment, and key derivation.

AES-GCM without key commitment

Algorithm suites without key commitment do not validate the data key before decrypting. As a result, these algorithm suites might decrypt a single ciphertext into different plaintext messages. However, because algorithm suites with key commitment produce a [slightly larger \(+30 bytes\) encrypted message](#) (p. 224) and take longer to process, they might not be the best choice for every application.

The AWS Encryption SDK supports an algorithm suite with key derivation, key commitment, signing, and one with key derivation and key commitment, but not signing. We do not recommend using an algorithm suite without key commitment. If you must, we recommend an algorithm suite with key derivation and key commitment, but not signing. However, if your application performance profile supports using an algorithm suite, using an algorithm suite with key commitment, key derivation, and signing is a best practice.

AES-GCM without signing

Algorithm suites without signing lack the ECDSA signature that provides authenticity and non-repudiation. Use these suites only when the users who encrypt data and those who decrypt data are equally trusted.

When using an algorithm suite without signing, we recommend that you choose one with key derivation and key commitment.

AES-GCM without key derivation

Algorithm suites without key derivation use the data encryption key as the AES-GCM encryption key, instead of using a key derivation function to derive a unique key. We discourage using this suite to generate ciphertext, but the AWS Encryption SDK supports it for compatibility reasons.

For more information about how these suites are represented and used in the library, see [the section called “Algorithms reference” \(p. 241\)](#).

Using the AWS Encryption SDK with AWS KMS

To use the AWS Encryption SDK, you need to configure [keyrings \(p. 7\)](#) or [master key providers \(p. 7\)](#) with wrapping keys. If you don't have a key infrastructure, we recommend using [AWS Key Management Service \(AWS KMS\)](#). Many of the code examples in the AWS Encryption SDK require an [AWS KMS key](#).

To interact with AWS KMS, the AWS Encryption SDK requires the AWS SDK for your preferred programming language. The AWS Encryption SDK client library works with the AWS SDKs to support master keys stored in AWS KMS.

To prepare to use the AWS Encryption SDK with AWS KMS

1. Create an AWS account. To learn how, see [How do I create and activate a new Amazon Web Services account?](#) in the AWS Knowledge Center.
2. Create a symmetric encryption AWS KMS key. For help, see [Creating Keys](#) in the *AWS Key Management Service Developer Guide*.

Tip

To use the AWS KMS key programmatically, you will need the key ID or Amazon Resource Name (ARN) of the AWS KMS key. For help finding the ID or ARN of an AWS KMS key, see [Finding the Key ID and ARN](#) in the *AWS Key Management Service Developer Guide*.

3. Create an IAM user with an access key. To learn how, see [Creating IAM Users](#) in the *IAM User Guide*. When you create the user, for **Access type**, choose **Programmatic access**. After you create the user, choose **Download.csv** to save the AWS access key that represents your user credentials. [Store the file in a secure location](#).

We recommend that you use AWS Identity and Access Management (IAM) access keys instead of AWS (root) account access keys. IAM lets you securely control access to AWS services and resources in your AWS account. For detailed best practice guidance, see [Best Practices for Managing AWS Access Keys](#).

The `Download.csv` file contains an AWS access key ID and a secret access key that represents the AWS credentials of the user that you created. When you write code without using an AWS SDK, you use your access key to sign your requests to AWS. The signature assures AWS that the request came from you unchanged. However, when you use an AWS SDK, such as the AWS SDK for Java, the SDK signs all requests to AWS for you.

4. Set your AWS credentials using the instructions in the [AWS SDK for Java](#), [AWS SDK for JavaScript](#), [AWS SDK for Python \(Boto\)](#) or [AWS SDK for C++](#) (for C), and the AWS access key in the `Download.csv` file that you downloaded in step 3.

This procedure allows AWS SDKs to sign requests to AWS for you. Code samples in the AWS Encryption SDK that interact with AWS KMS assume that you have completed this step.

5. Download and install the AWS Encryption SDK. To learn how, see the installation instructions for the [programming language \(p. 68\)](#) that you want to use.

Best practices for the AWS Encryption SDK

The AWS Encryption SDK is designed to make it easy for you to protect your data using industry standards and best practices. While many best practices are selected for you in default values, some practices are optional but recommended whenever it's practical.

Use the latest version

When you start using the AWS Encryption SDK, use the latest version offered in your preferred [programming language \(p. 68\)](#). If you've been using the AWS Encryption SDK, upgrade to each latest version as soon as possible. This assures that you're using the recommended configuration and taking advantage of new security properties to protect your data. For details about supported versions, including guidance for migration and deployment, see [Support and maintenance \(p. 3\)](#) and [Versions of the AWS Encryption SDK \(p. 194\)](#).

If a new version deprecates elements in your code, replace them as soon as you can. Deprecation warnings and code comments typically recommend a good alternative.

To make significant upgrades easier and less prone to error, we occasionally provide a temporary or transitional release. Use these releases, and their accompanying documentation, to assure that you can upgrade your application without disrupting your production workflow.

Use default values

The AWS Encryption SDK designs best practices into its default values. Whenever possible, use them. For cases where the default is impractical, we provide alternatives, such as algorithm suites without signing. We also provide opportunities to advanced users for customization, such as custom keyrings, master key providers, and cryptographic material managers (CMMs). Use these advanced alternatives cautiously and have your choices verified by a security engineer whenever possible.

Use an encryption context

To improve the security of your cryptographic operations, include an [encryption context \(p. 8\)](#) with a meaningful value in all requests to encrypt data. Using an encryption context is optional, but it is a cryptographic best practice that we recommend. An encryption context provides additional authenticated data (AAD) for authenticated encryption in the AWS Encryption SDK. Although it is not secret, the encryption context can help you to [protect the integrity and authenticity](#) of your encrypted data.

In the AWS Encryption SDK, you specify an encryption context only when encrypting. When decrypting, the AWS Encryption SDK uses the encryption context in the header of the encrypted message that the AWS Encryption SDK returns. Before your application returns plaintext data, verify that the encryption context that you used to encrypt the message is included in the encryption context that was used to decrypt the message. For details, see the examples in your programming language.

When you use the command line interface, the AWS Encryption SDK verifies the encryption context for you.

Protect your wrapping keys

The AWS Encryption SDK generates a unique data key to encrypt each plaintext message. Then it encrypts the data key with wrapping keys that you supply. If your wrapping keys are lost or deleted, your encrypted data is unrecoverable. If your keys are not secured, your data might be vulnerable.

Use wrapping keys that are protected by a secure key infrastructure, such as [AWS Key Management Service](#) (AWS KMS). When using raw AES or raw RSA keys, use a source of randomness and durable

storage that meets your security requirements. Generating and storing wrapping keys in a hardware security module (HSM), or a service that provides HSMs, such as AWS CloudHSM, is a best practice.

Use the authorization mechanisms of your key infrastructure to limit access to your wrapping keys to only the users that require it. Implement best practice principles, such as least privilege. When using AWS KMS keys, use key policies and IAM policies that implement [best practice principles](#).

Specify your wrapping keys

It's always a best practice to [specify your wrapping keys \(p. 20\)](#) explicitly when decrypting, as well as encrypting. When you do, the AWS Encryption SDK uses only the keys that you specify. This practice assures that you only use the encryption keys that you intend. For AWS KMS wrapping keys, it also improves performance by preventing you from inadvertently using keys in a different AWS account or Region, or attempting to decrypt with keys that you don't have permission to use.

When encrypting, the keyrings and master key providers that the AWS Encryption SDK supplies require that you specify wrapping keys. They use all and only the wrapping keys you specify. You are also required to specify wrapping keys when encrypting and decrypting with raw AES keyrings, raw RSA keyrings, and JCEMasterKeys.

However, when decrypting with AWS KMS keyrings and master key providers, you are not required to specify wrapping keys. The AWS Encryption SDK can get the key identifier from the metadata of the encrypted data key. But specifying wrapping keys is a best practice that we recommend.

To support this best practice when working with AWS KMS wrapping keys, we recommend the following:

- Use AWS KMS keyrings that specify wrapping keys. When encrypting and decrypting, these keyrings use only the specified wrapping keys you specify.
- When using AWS KMS master keys and master key providers, use the strict mode constructors introduced in [version 1.7.x \(p. 195\)](#) of the AWS Encryption SDK. They create providers that encrypt and decrypt only with the wrapping keys you specify. Constructors for master key providers that always decrypt with any wrapping key are deprecated in version 1.7.x and deleted in version 2.0.x.

When specifying AWS KMS wrapping keys for decrypting is impractical, you can use discovery providers. The AWS Encryption SDK in C and JavaScript support [AWS KMS discovery keyrings \(p. 55\)](#). Master key providers with a discovery mode are available for Java and Python in versions 1.7.x and later. These discovery providers, which are used only for decrypting with AWS KMS wrapping keys, explicitly direct the AWS Encryption SDK to use any wrapping key that encrypted a data key.

If you must use a discovery provider, use its *discovery filter* features to limit the wrapping keys they use. For example, the [AWS KMS regional discovery keyring \(p. 56\)](#) uses only the wrapping keys in a particular AWS Region. You can also configure AWS KMS keyrings and AWS KMS [master key providers \(p. 207\)](#) to use only the [wrapping keys \(p. 209\)](#) in particular AWS accounts. Also, as always, use key policies and IAM policies to control access to your AWS KMS wrapping keys.

Use digital signatures

It's a best practice to use an algorithm suite with signing. [Digital signatures \(p. 12\)](#) verify the message sender was authorized to send the message and protect the integrity of the message. All versions of the AWS Encryption SDK use algorithm suites with signing by default.

If your security requirements don't include digital signatures, you can select an algorithm suite without digital signatures. However, we recommend using digital signatures, especially when one group of users encrypts data and a different set of users decrypts that data.

Use key commitment

It is a best practice to use the key commitment security feature. By verifying the identity of the unique [data key \(p. 6\)](#) that encrypted your data, [key commitment \(p. 10\)](#) prevents you from decrypting any ciphertext that might result in more than one plaintext message.

The AWS Encryption SDK provides full support for encrypting and decrypting with key commitment beginning in [version 2.0.x \(p. 197\)](#). By default, all of your messages are encrypted and decrypted with key commitment. [Version 1.7.x \(p. 195\)](#) of the AWS Encryption SDK can decrypt ciphertexts with key commitment. It is designed to help users of earlier versions deploy version 2.0.x successfully.

Support for key commitment includes [new algorithm suites \(p. 13\)](#) and a [new message format \(p. 224\)](#) that produces a ciphertext only 30 bytes larger than a ciphertext without key commitment. The design minimizes its impact on performance so most users can enjoy the benefits of key commitment. If your application is very sensitive to size and performance, you might decide to use the [commitment policy \(p. 11\)](#) setting to disable key commitment or allow the AWS Encryption SDK to decrypt messages without commitment, but do so only if you must.

Limit the number of encrypted data keys

It's a best practice to [limit the number of encrypted data keys \(p. 41\)](#) in messages that you decrypt, especially messages from untrusted sources. Decrypting a message with numerous encrypted data keys that you can't decrypt can cause extended delays, run up expenses, throttle your application and others that share your account, and potentially exhaust your key infrastructure. Without limits, an encrypted message can have up to 65,535 ($2^{16} - 1$) encrypted data keys. For details, see [Limit encrypted data keys \(p. 41\)](#).

For more information about the AWS Encryption SDK security features that underlie these best practices, see [Improved client-side encryption: Explicit KeyIds and key commitment](#) in the *AWS Security Blog*.

Configuring the AWS Encryption SDK

The AWS Encryption SDK is designed to be easy to use. Although the AWS Encryption SDK has several configuration options, the default values are carefully chosen to be practical and secure for most applications. However, you might need to adjust your configuration to improve performance or include a custom feature in your design.

When configuring your implementation, review the AWS Encryption SDK [best practices \(p. 17\)](#) and implement as many as you can.

Topics

- [Select a programming language \(p. 20\)](#)
- [Select wrapping keys \(p. 20\)](#)
- [Use multi-Region AWS KMS keys \(p. 21\)](#)
- [Choosing an algorithm suite \(p. 35\)](#)
- [Limit encrypted data keys \(p. 41\)](#)
- [Work with streaming data \(p. 44\)](#)
- [Cache data keys \(p. 44\)](#)

Select a programming language

The AWS Encryption SDK is available in multiple [programming languages \(p. 68\)](#). The language implementations are designed to be fully interoperable and to offer the same features, although they might be implemented in different ways. Typically, you use the library that is compatible with your application. However, you might select a programming language for a particular implementation. For example, if you prefer to work with [keyrings \(p. 45\)](#), you might choose the AWS Encryption SDK for C or the AWS Encryption SDK for JavaScript.

Select wrapping keys

The AWS Encryption SDK generates a unique symmetric data key to encrypt each message. Unless you are using [data key caching \(p. 152\)](#), you don't need to configure, manage, or use the data keys. The AWS Encryption SDK does it for you.

However, you must select one or more wrapping keys to encrypt each data key. The AWS Encryption SDK supports AES symmetric keys and RSA asymmetric keys in different sizes. It also supports [AWS Key Management Service \(AWS KMS\)](#) symmetric encryption AWS KMS keys. You are responsible for the safety and durability of your wrapping keys, so we recommend that you use an encryption key in a hardware security module or a key infrastructure service, such as AWS KMS.

To specify your wrapping keys for encryption and decryption, you use a keyring (C and JavaScript) or a master key provider (Java, Python, AWS Encryption CLI). You can specify one wrapping key or multiple wrapping keys of the same or different types. If you use multiple wrapping keys to wrap a data key, each wrapping key will encrypt a copy of the same data key. The encrypted data keys (one per wrapping key)

are stored with the encrypted data in the encrypted message that the AWS Encryption SDK returns. To decrypt the data, the AWS Encryption SDK must first use one of your wrapping keys to decrypt an encrypted data key.

To specify an AWS KMS key in a keyring or master key provider, use a supported AWS KMS key identifier. For details about the key identifiers for an AWS KMS key, see [Key Identifiers](#) in the *AWS Key Management Service Developer Guide*.

- When encrypting with the AWS Encryption SDK for Java, AWS Encryption SDK for JavaScript, AWS Encryption SDK for Python, or the AWS Encryption CLI, you can use any valid key identifier (key ID, key ARN, alias name, or alias ARN) for a KMS key. When encrypting with the AWS Encryption SDK for C, you can only use a key ID or key ARN.

If you specify an alias name or alias ARN for a KMS key when encrypting, the AWS Encryption SDK saves the key ARN currently associated with that alias; it does not save the alias. Changes to the alias don't affect the KMS key used to decrypt your data keys.

- When decrypting in strict mode (where you specify particular wrapping keys), you must use a key ARN to identify AWS KMS keys. This requirement applies to all language implementations of the AWS Encryption SDK.

When you encrypt with an AWS KMS keyring, the AWS Encryption SDK stores the key ARN of the AWS KMS key in the metadata of the encrypted data key. When decrypting in strict mode, the AWS Encryption SDK verifies that the same key ARN appears in the keyring (or master key provider) before it attempts to use the wrapping key to decrypt the encrypted data key. If you use a different key identifier, the AWS Encryption SDK will not recognize or use the AWS KMS key, even if the identifiers refer to the same key.

To specify a [raw AES key \(p. 59\)](#) or a [raw RSA key pair \(p. 61\)](#) as a wrapping key in a keyring, you must specify a namespace and a name. In a master key provider, the `Provider ID` is the equivalent of the namespace and the `Key ID` is the equivalent of the name. When decrypting, you must use the exact same namespace and name for each raw wrapping key as you used when encrypting. If you use a different namespace or name, the AWS Encryption SDK will not recognize or use the wrapping key, even if the key material is the same.

Use multi-Region AWS KMS keys

You can use AWS Key Management Service (AWS KMS) multi-Region keys as wrapping keys in the AWS Encryption SDK. If you encrypt with a multi-Region key in one AWS Region, you can decrypt using a related multi-Region key in a different AWS Region. Support for multi-Region keys is introduced in version 2.3.x of the AWS Encryption SDK and version 3.0.x of the AWS Encryption CLI.

AWS KMS multi-Region keys are a set of AWS KMS keys in different AWS Regions that have the same key material and key ID. You can use these *related* keys as though they were the same key in different Regions. Multi-Region keys support common disaster recovery and backup scenarios that require encrypting in one Region and decrypting in a different Region without making a cross-Region call to AWS KMS. For information about multi-Region keys, see [Using multi-Region keys](#) in the *AWS Key Management Service Developer Guide*.

To support multi-Region keys, the AWS Encryption SDK includes AWS KMS multi-Region-aware keyrings and master key providers. The new multi-Region-aware symbol in each programming language supports both single-Region and multi-Region keys.

- For single-Region keys, the multi-Region-aware symbol behaves just like the single-Region AWS KMS keyring and master key provider. It attempts to decrypt ciphertext only with the single-Region key that encrypted the data.

- For multi-Region keys, the multi-Region-aware symbol attempts to decrypt ciphertext with the same multi-Region key that encrypted the data or with the related multi-Region key in the Region you specify.

In the multi-Region-aware keyrings and master key providers that take more than one KMS key, you can specify multiple single-Region and multi-Region keys. However, you can specify only one key from each set of related multi-Region keys. If you specify more than one key identifier with the same key ID, the constructor call fails.

You can also use a multi-Region key with the standard, single-Region AWS KMS keyrings and master key providers. However, you must use the same multi-Region key in the same Region to encrypt and decrypt. The single-Region keyrings and master key providers attempt to decrypt ciphertext only with the keys that encrypted the data.

The following examples show how to encrypt and decrypt data using multi-Region keys and the new multi-Region-aware keyrings and master key providers. These examples encrypt data in the `us-east-1` Region and decrypt the data in the `us-west-2` Region using related multi-Region keys in each Region. Before running these examples, replace the example multi-Region key ARN with a valid value from your AWS account.

C

To encrypt with a multi-Region key, use the `Aws::Cryptosdk::KmsMrkAwareSymmetricKeyring::Builder()` method to instantiate the keyring. Specify a multi-Region key.

This simple example does not include an [encryption context \(p. 8\)](#). For an example that uses an encryption context in C, see [Encrypting and decrypting strings \(p. 72\)](#).

For a complete example, see [kms_multi_region_keys.cpp](#) in the AWS Encryption SDK for C repository on GitHub.

```
/* Encrypt with a multi-Region KMS key in us-east-1 */

/* Load error strings for debugging */
aws_cryptosdk_load_error_strings();

/* Initialize a multi-Region keyring */
const char *mrk_us_east_1 = "arn:aws:kms:us-east-1:111122223333:key/
mrk-1234abcd12ab34cd56ef1234567890ab";

struct aws_cryptosdk_keyring *mrk_keyring =
    Aws::Cryptosdk::KmsMrkAwareSymmetricKeyring::Builder().Build(mrk_us_east_1);

/* Create a session; release the keyring */
struct aws_cryptosdk_session *session =
    aws_cryptosdk_session_new_from_keyring_2(aws_default_allocator(),
    AWS_CRYPTOSDK_ENCRYPT, mrk_keyring);

aws_cryptosdk_keyring_release(mrk_keyring);

/* Encrypt the data
 * aws_cryptosdk_session_process_full is designed for non-streaming data
 */
aws_cryptosdk_session_process_full(
    session, ciphertext, ciphertext_buf_sz, &ciphertext_len, plaintext,
    plaintext_len));

/* Clean up the session */
aws_cryptosdk_session_destroy(session);
```

C# / .NET

To encrypt with a multi-Region key in the US East (N. Virginia) (us-east-1) Region, instantiate a `CreateAwsKmsMrkKeyringInput` object with a key identifier for the multi-Region key and an AWS KMS client for the specified Region. Then use the `CreateAwsKmsMrkKeyring()` method to create the keyring.

The `CreateAwsKmsMrkKeyring()` method creates a keyring with exactly one multi-Region key. To encrypt with multiple wrapping keys, including a multi-Region key, use the `CreateAwsKmsMrkMultiKeyring()` method.

For a complete example, see [AwsKmsMrkKeyringExample.cs](#) in the AWS Encryption SDK for .NET repository on GitHub.

```
//Encrypt with a multi-Region KMS key in us-east-1 Region

// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

// Multi-Region keys have a distinctive key ID that begins with 'mrk'
// Specify a multi-Region key in us-east-1
string mrkUSEast1 = "arn:aws:kms:us-east-1:111122223333:key/
mrk-1234abcd12ab34cd56ef1234567890ab";

// Create the keyring
// You can specify the Region or get the Region from the key ARN
var createMrkEncryptKeyringInput = new CreateAwsKmsMrkKeyringInput
{
    KmsClient = new AmazonKeyManagementServiceClient(RegionEndpoint.USEast1),
    KmsKeyId = mrkUSEast1
};
var mrkEncryptKeyring =
    materialProviders.CreateAwsKmsMrkKeyring(createMrkEncryptKeyringInput);

// Define the encryption context
var encryptionContext = new Dictionary<string, string>()
{
    {"purpose", "test"}
};

// Encrypt your plaintext data.
var encryptInput = new EncryptInput
{
    Plaintext = plaintext,
    Keyring = mrkEncryptKeyring,
    EncryptionContext = encryptionContext
};
var encryptOutput = encryptionSdk.Encrypt(encryptInput);
```

AWS Encryption CLI

This example encrypts the `hello.txt` file under a multi-Region key in the us-east-1 Region. Because the example specifies a key ARN with a Region element, this example doesn't use the **region** attribute of the `--wrapping-keys` parameter.

When the key ID of the wrapping key doesn't specify a Region, you can use the **region** attribute of the `--wrapping-keys` to specify the region, such as `--wrapping-keys key=$keyID region=us-east-1`.

```
# Encrypt with a multi-Region KMS key in us-east-1 Region

# To run this example, replace the fictitious key ARN with a valid value.
$ mrkUSEast1=arn:aws:kms:us-east-1:111122223333:key/
mrk-1234abcd12ab34cd56ef1234567890ab

$ aws-encryption-cli --encrypt \
    --input hello.txt \
    --wrapping-keys key=$mrkUSEast1 \
    --metadata-output ~/metadata \
    --encryption-context purpose=test \
    --output .
```

Java

To encrypt with a multi-Region key, instantiate an `AwsKmsMrkAwareMasterKeyProvider` and specify a multi-Region key.

For a complete example, see [BasicMultiRegionKeyEncryptionExample.java](#) in the AWS Encryption SDK for Java repository on GitHub.

```
//Encrypt with a multi-Region KMS key in us-east-1 Region

// Instantiate the client
final AwsCrypto crypto = AwsCrypto.builder()
    .withCommitmentPolicy(CommitmentPolicy.RequireEncryptRequireDecrypt)
    .build();

// Multi-Region keys have a distinctive key ID that begins with 'mrk'
// Specify a multi-Region key in us-east-1
final String mrkUSEast1 = "arn:aws:kms:us-east-1:111122223333:key/
mrk-1234abcd12ab34cd56ef1234567890ab";

// Instantiate an AWS KMS master key provider in strict mode for multi-Region keys
// Configure it to encrypt with the multi-Region key in us-east-1
final AwsKmsMrkAwareMasterKeyProvider kmsMrkProvider = AwsKmsMrkAwareMasterKeyProvider
    .builder()
    .buildStrict(mrkUSEast1);

// Create an encryption context
final Map<String, String> encryptionContext = Collections.singletonMap("Purpose",
    "Test");

// Encrypt your plaintext data
final CryptoResult<byte[], AwsKmsMrkAwareMasterKey> encryptResult = crypto.encryptData(
    kmsMrkProvider,
    encryptionContext,
    sourcePlaintext);
byte[] ciphertext = encryptResult.getResult();
```

JavaScript Browser

To encrypt with a multi-Region key, use the `buildAwsKmsMrkAwareStrictMultiKeyringBrowser()` method to create the keyring and specify a multi-Region key.

For a complete example, see [kms_multi_region_simple.ts](#) in the AWS Encryption SDK for JavaScript repository on GitHub.

```
/* Encrypt with a multi-Region KMS key in us-east-1 Region */
```

```
import {
  buildAwsKmsMrkAwareStrictMultiKeyringBrowser,
  buildClient,
  CommitmentPolicy,
  KMS,
} from '@aws-crypto/client-browser'

/* Instantiate an AWS Encryption SDK client */
const { encrypt } = buildClient(
  CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT
)

declare const credentials: {
  accessKeyId: string
  secretAccessKey: string
  sessionToken: string
}

/* Instantiate an AWS KMS client
 * The AWS Encryption SDK for JavaScript gets the Region from the key ARN
 */
const clientProvider = (region: string) => new KMS({ region, credentials })

/* Specify a multi-Region key in us-east-1 */
const multiRegionUsEastKey =
  'arn:aws:kms:us-east-1:111122223333:key/mrk-1234abcd12ab34cd56ef1234567890ab'

/* Instantiate the keyring */
const encryptKeyring = buildAwsKmsMrkAwareStrictMultiKeyringBrowser({
  generatorKeyId: multiRegionUsEastKey,
  clientProvider,
})

/* Set the encryption context */
const context = {
  purpose: 'test',
}

/* Test data to encrypt */
const cleartext = new Uint8Array([1, 2, 3, 4, 5])

/* Encrypt the data */
const { result } = await encrypt(encryptKeyring, cleartext, {
  encryptionContext: context,
})
```

JavaScript Node.js

To encrypt with a multi-Region key, use the `buildAwsKmsMrkAwareStrictMultiKeyringNode()` method to create the keyring and specify a multi-Region key.

For a complete example, see [kms_multi_region_simple.ts](#) in the AWS Encryption SDK for JavaScript repository on GitHub.

```
//Encrypt with a multi-Region KMS key in us-east-1 Region

import { buildClient } from '@aws-crypto/client-node'

/* Instantiate the AWS Encryption SDK client
const { encrypt } = buildClient(
  CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT
```

```
)

/* Test string to encrypt */
const cleartext = 'asdf'

/* Multi-Region keys have a distinctive key ID that begins with 'mrk'
 * Specify a multi-Region key in us-east-1
 */
const multiRegionUsEastKey =
  'arn:aws:kms:us-east-1:111122223333:key/mrk-1234abcd12ab34cd56ef1234567890ab'

/* Create an AWS KMS keyring */
const mrkEncryptKeyring = buildAwsKmsMrkAwareStrictMultiKeyringNode({
  generatorKeyId: multiRegionUsEastKey,
})

/* Specify an encryption context */
const context = {
  purpose: 'test',
}

/* Create an encryption keyring */
const { result } = await encrypt(mrkEncryptKeyring, cleartext, {
  encryptionContext: context,
})
```

Python

To encrypt with an AWS KMS multi-Region key, use the `MRKAwareStrictAwsKmsMasterKeyProvider()` method and specify a multi-Region key.

For a complete example, see [mrk_aware_kms_provider.py](#) in the AWS Encryption SDK for Python repository on GitHub.

```
* Encrypt with a multi-Region KMS key in us-east-1 Region

# Instantiate the client
client =
  aws_encryption_sdk.EncryptionSDKClient(commitment_policy=CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_

# Specify a multi-Region key in us-east-1
mrk_us_east_1 = "arn:aws:kms:us-east-1:111122223333:key/
mrk-1234abcd12ab34cd56ef1234567890ab"

# Use the multi-Region method to create the master key provider
# in strict mode
strict_mrk_key_provider = MRKAwareStrictAwsKmsMasterKeyProvider(
  key_ids=[mrk_us_east_1]
)

# Set the encryption context
encryption_context = {
  "purpose": "test"
}

# Encrypt your plaintext data
ciphertext, encrypt_header = client.encrypt(
  source=source_plaintext,
  encryption_context=encryption_context,
  key_provider=strict_mrk_key_provider
)
```

Next, move your ciphertext to the `us-west-2` Region. You don't need to re-encrypt the ciphertext.

To decrypt the ciphertext in strict mode in the `us-west-2` Region, instantiate the multi-Region-aware symbol with the key ARN of the related multi-Region key in the `us-west-2` Region. If you specify the key ARN of a related multi-Region key in a different Region (including `us-east-1`, where it was encrypted), the multi-Region-aware symbol will make a cross-Region call for that AWS KMS key.

When decrypting in strict mode, the multi-Region-aware symbol requires a key ARN. It accepts only one key ARN from each set of related multi-Region keys.

Before running these examples, replace the example multi-Region key ARN with a valid value from your AWS account.

C

To decrypt in strict mode with a multi-Region key, use the `Aws::Cryptosdk::KmsMrkAwareSymmetricKeyring::Builder()` method to instantiate the keyring. Specify the related multi-Region key in the local (`us-west-2`) Region.

For a complete example, see [kms_multi_region_keys.cpp](#) in the AWS Encryption SDK for C repository on GitHub.

```
/* Decrypt with a related multi-Region KMS key in us-west-2 Region */

/* Load error strings for debugging */
aws_cryptosdk_load_error_strings();

/* Initialize a multi-Region keyring */
const char *mrk_us_west_2 = "arn:aws:kms:us-west-2:111122223333:key/mrk-1234abcd12ab34cd56ef1234567890ab";

struct aws_cryptosdk_keyring *mrk_keyring =
    Aws::Cryptosdk::KmsMrkAwareSymmetricKeyring::Builder().Build(mrk_us_west_2);

/* Create a session; release the keyring */
struct aws_cryptosdk_session *session =
    aws_cryptosdk_session_new_from_keyring_2(aws_default_allocator(),
    AWS_CRYPTOSDK_ENCRYPT, mrk_keyring);

aws_cryptosdk_session_set_commitment_policy(session,
    COMMITMENT_POLICY_REQUIRE_ENCRYPT_REQUIRE_DECRYPT);

aws_cryptosdk_keyring_release(mrk_keyring);

/* Decrypt the ciphertext
 * aws_cryptosdk_session_process_full is designed for non-streaming data
 */
aws_cryptosdk_session_process_full(
    session, plaintext, plaintext_buf_sz, &plaintext_len, ciphertext, ciphertext_len));

/* Clean up the session */
aws_cryptosdk_session_destroy(session);
```

C# / .NET

To decrypt in strict mode with a single multi-Region key, use the same constructors and methods that you used to assemble the input and create the keyring for encrypting. Instantiate a `CreateAwsKmsMrkKeyringInput` object with the key ARN of a related multi-Region key and an AWS KMS client for the US West (Oregon) (`us-west-2`) Region. Then use the `CreateAwsKmsMrkKeyring()` method to create a multi-Region keyring with one multi-Region KMS key.

For a complete example, see [AwsKmsMrkKeyringExample.cs](#) in the AWS Encryption SDK for .NET repository on GitHub.

```
// Decrypt with a related multi-Region KMS key in us-west-2 Region

// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

// Specify the key ARN of the multi-Region key in us-west-2
string mrkUSWest2 = "arn:aws:kms:us-west-2:111122223333:key/
mrk-1234abcd12ab34cd56ef1234567890ab";

// Instantiate the keyring input
// You can specify the Region or get the Region from the key ARN
var createMrkDecryptKeyringInput = new CreateAwsKmsMrkKeyringInput
{
    KmsClient = new AmazonKeyManagementServiceClient(RegionEndpoint.USWest2),
    KmsKeyId = mrkUSWest2
};

// Create the multi-Region keyring
var mrkDecryptKeyring =
    materialProviders.CreateAwsKmsMrkKeyring(createMrkDecryptKeyringInput);

// Decrypt the ciphertext
var decryptInput = new DecryptInput
{
    Ciphertext = ciphertext,
    Keyring = mrkDecryptKeyring
};
var decryptOutput = encryptionSdk.Decrypt(decryptInput);
```

AWS Encryption CLI

To decrypt with the related multi-Region key in the us-west-2 Region, use the **key** attribute of the **--wrapping-keys** parameter to specify its key ARN.

```
# Decrypt with a related multi-Region KMS key in us-west-2 Region

# To run this example, replace the fictitious key ARN with a valid value.
$ mrkUSWest2=arn:aws:kms:us-west-2:111122223333:key/
mrk-1234abcd12ab34cd56ef1234567890ab

$ aws-encryption-cli --decrypt \
    --input hello.txt.encrypted \
    --wrapping-keys key=$mrkUSWest2 \
    --commitment-policy require-encrypt-require-decrypt \
    --encryption-context purpose=test \
    --metadata-output ~/metadata \
    --max-encrypted-data-keys 1 \
    --buffer \
    --output .
```

Java

To decrypt in strict mode, instantiate an `AwsKmsMrkAwareMasterKeyProvider` and specify the related multi-Region key in the local (us-west-2) Region.

For a complete example, see [BasicMultiRegionKeyEncryptionExample.java](#) in the AWS Encryption SDK for Java repository on GitHub.

```
// Decrypt with a related multi-Region KMS key in us-west-2 Region
```

```
// Instantiate the client
final AwsCrypto crypto = AwsCrypto.builder()
    .withCommitmentPolicy(CommitmentPolicy.RequireEncryptRequireDecrypt)
    .build();

// Related multi-Region keys have the same key ID. Their key ARNs differs only in the
// Region field.
String mrkUSWest2 = "arn:aws:kms:us-west-2:111122223333:key/
mrk-1234abcd12ab34cd56ef1234567890ab";

// Use the multi-Region method to create the master key provider
// in strict mode
AwsKmsMrkAwareMasterKeyProvider kmsMrkProvider =
    AwsKmsMrkAwareMasterKeyProvider.builder()
        .buildStrict(mrkUSWest2);

// Decrypt your ciphertext
CryptoResult<byte[], AwsKmsMrkAwareMasterKey> decryptResult = crypto.decryptData(
    kmsMrkProvider,
    ciphertext);
byte[] decrypted = decryptResult.getResult();
```

JavaScript Browser

To decrypt in strict mode, use the `buildAwsKmsMrkAwareStrictMultiKeyringBrowser()` method to create the keyring and specify the related multi-Region key in the local (us-west-2) Region.

For a complete example, see [kms_multi_region_simple.ts](#) in the AWS Encryption SDK for JavaScript repository on GitHub.

```
/* Decrypt with a related multi-Region KMS key in us-west-2 Region */

import {
    buildAwsKmsMrkAwareStrictMultiKeyringBrowser,
    buildClient,
    CommitmentPolicy,
    KMS,
} from '@aws-crypto/client-browser'

/* Instantiate an AWS Encryption SDK client */
const { decrypt } = buildClient(
    CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT
)

declare const credentials: {
    accessKeyId: string
    secretAccessKey: string
    sessionToken: string
}

/* Instantiate an AWS KMS client
 * The AWS Encryption SDK for JavaScript gets the Region from the key ARN
 */
const clientProvider = (region: string) => new KMS({ region, credentials })

/* Specify a multi-Region key in us-west-2 */
const multiRegionUsWestKey =
    'arn:aws:kms:us-west-2:111122223333:key/mrk-1234abcd12ab34cd56ef1234567890ab'

/* Instantiate the keyring */
const mrkDecryptKeyring = buildAwsKmsMrkAwareStrictMultiKeyringBrowser({
```

```
        generatorKeyId: multiRegionUsWestKey,  
        clientProvider,  
    })  
  
    /* Decrypt the data */  
    const { plaintext, messageHeader } = await decrypt(mrkDecryptKeyring, result)
```

JavaScript Node.js

To decrypt in strict mode, use the `buildAwsKmsMrkAwareStrictMultiKeyringNode()` method to create the keyring and specify the related multi-Region key in the local (us-west-2) Region.

For a complete example, see [kms_multi_region_simple.ts](#) in the AWS Encryption SDK for JavaScript repository on GitHub.

```
/* Decrypt with a related multi-Region KMS key in us-west-2 Region */  
  
import { buildClient } from '@aws-crypto/client-node'  
  
/* Instantiate the client  
const { decrypt } = buildClient(  
    CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT  
)  
  
/* Multi-Region keys have a distinctive key ID that begins with 'mrk'  
 * Specify a multi-Region key in us-east-1  
 */  
const multiRegionUsWestKey =  
    'arn:aws:kms:us-west-2:111122223333:key/mrk-1234abcd12ab34cd56ef1234567890ab'  
  
/* Create an AWS KMS keyring */  
const mrkDecryptKeyring = buildAwsKmsMrkAwareStrictMultiKeyringNode({  
    generatorKeyId: multiRegionUsWestKey,  
})  
  
/* Decrypt your ciphertext */  
const { plaintext, messageHeader } = await decrypt(decryptKeyring, result)
```

Python

To decrypt in strict mode, use the `MRKAwareStrictAwsKmsMasterKeyProvider()` method to create the master key provider. Specify the related multi-Region key in the local (us-west-2) Region.

For a complete example, see [mrk_aware_kms_provider.py](#) in the AWS Encryption SDK for Python repository on GitHub.

```
# Decrypt with a related multi-Region KMS key in us-west-2 Region  
  
# Instantiate the client  
client =  
    aws_encryption_sdk.EncryptionSDKClient(commitment_policy=CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT)  
  
# Related multi-Region keys have the same key ID. Their key ARNs differs only in the  
# Region field  
mrk_us_west_2 = "arn:aws:kms:us-west-2:111122223333:key/  
mrk-1234abcd12ab34cd56ef1234567890ab"  
  
# Use the multi-Region method to create the master key provider  
# in strict mode  
strict_mrk_key_provider = MRKAwareStrictAwsKmsMasterKeyProvider(  
    key_ids=[mrk_us_west_2]  
)
```

```
# Decrypt your ciphertext
plaintext, _ = client.decrypt(
    source=ciphertext,
    key_provider=strict_mrk_key_provider
)
```

You can also decrypt in *discovery mode* with AWS KMS multi-Region keys. When decrypting in discovery mode, you don't specify any AWS KMS keys. (For information about single-Region AWS KMS discovery keyrings, see [Using an AWS KMS discovery keyring \(p. 55\)](#).)

If you encrypted with a multi-Region key, the multi-Region-aware symbol in discovery mode will try to decrypt by using a related multi-Region key in the local Region. If none exists; the call fails. In discovery mode, the AWS Encryption SDK will not attempt a cross-Region call for the multi-Region key used for encryption.

Note

If you use a multi-Region-aware symbol in discovery mode to encrypt data, the encrypt operation fails.

The following example shows how to decrypt with the multi-Region-aware symbol in discovery mode. Because you don't specify an AWS KMS key, the AWS Encryption SDK must get the Region from a different source. When possible, specify the local Region explicitly. Otherwise, the AWS Encryption SDK gets the local Region from the Region configured in the AWS SDK for your programming language.

Before running these examples, replace the example account ID and multi-Region key ARN with valid values from your AWS account.

C

To decrypt in discovery mode with a multi-Region key, use the `Aws::Cryptosdk::KmsKeyring::DiscoveryFilter::Builder()` method. To specify the local Region, define a `ClientConfiguration` and specify it in the AWS KMS client.

For a complete example, see [kms_multi_region_keys.cpp](#) in the AWS Encryption SDK for C repository on GitHub.

```
/* Decrypt in discovery mode with a multi-Region KMS key */

/* Load error strings for debugging */
aws_cryptosdk_load_error_strings();

/* Construct a discovery filter for the account and partition. The
 * filter is optional, but it's a best practice that we recommend.
 */
const char *account_id = "111122223333";
const char *partition = "aws";
const std::shared_ptr<Aws::Cryptosdk::KmsKeyring::DiscoveryFilter> discovery_filter =

    Aws::Cryptosdk::KmsKeyring::DiscoveryFilter::Builder(partition).AddAccount(account_id).Build();

/* Create an AWS KMS client in the desired region. */
const char *region = "us-west-2";

Aws::Client::ClientConfiguration client_config;
client_config.region = region;
const std::shared_ptr<Aws::KMS::KMSSClient> kms_client =
    Aws::MakeShared<Aws::KMS::KMSSClient>("AWS_SAMPLE_CODE", client_config);

struct aws_cryptosdk_keyring *mrk_keyring =
    Aws::Cryptosdk::KmsMrkAwareSymmetricKeyring::Builder()
        .WithKmsClient(kms_client)
```

```
        .BuildDiscovery(region, discovery_filter);

/* Create a session; release the keyring */
struct aws_cryptosdk_session *session =
    aws_cryptosdk_session_new_from_keyring_2(aws_default_allocator(),
        AWS_CRYPTOSDK_DECRYPT, mrk_keyring);

aws_cryptosdk_keyring_release(mrk_keyring);
commitment_policy=CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT
/* Decrypt the ciphertext
 *   aws_cryptosdk_session_process_full is designed for non-streaming data
 */
aws_cryptosdk_session_process_full(
    session, plaintext, plaintext_buf_sz, &plaintext_len, ciphertext, ciphertext_len));

/* Clean up the session */
aws_cryptosdk_session_destroy(session);
```

C# / .NET

To create a multi-Region-aware discovery keyring in the AWS Encryption SDK for .NET, instantiate a `CreateAwsKmsMrkDiscoveryKeyringInput` object that takes an AWS KMS client for a particular AWS Region, and an optional discovery filter that limits KMS keys to a particular AWS partition and account. Then call the `CreateAwsKmsMrkDiscoveryKeyring()` method with the input object. For a complete example, see [AwsKmsMrkDiscoveryKeyringExample.cs](#) in the AWS Encryption SDK for .NET repository on GitHub.

To create a multi-Region-aware discovery keyring for more than one AWS Region, use the `CreateAwsKmsMrkDiscoveryMultiKeyring()` method to create a multi-keyring, or use `CreateAwsKmsMrkDiscoveryKeyring()` to create several multi-Region-aware discovery keyrings and then use the `CreateMultiKeyring()` method to combine them in a multi-keyring.

For an example, see [AwsKmsMrkDiscoveryMultiKeyringExample.cs](#).

```
// Decrypt in discovery mode with a multi-Region KMS key

// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

List<string> account = new List<string> { "111122223333" };

// Instantiate the discovery filter
DiscoveryFilter mrkDiscoveryFilter = new DiscoveryFilter()
{
    AccountIds = account,
    Partition = "aws"
}

// Create the keyring
var createMrkDiscoveryKeyringInput = new CreateAwsKmsMrkDiscoveryKeyringInput
{
    KmsClient = new AmazonKeyManagementServiceClient(RegionEndpoint.USWest2),
    DiscoveryFilter = mrkDiscoveryFilter
};
var mrkDiscoveryKeyring =
    materialProviders.CreateAwsKmsMrkDiscoveryKeyring(createMrkDiscoveryKeyringInput);

// Decrypt the ciphertext
var decryptInput = new DecryptInput
{
```

```
Ciphertext = ciphertext,
Keyring = mrkDiscoveryKeyring
};
var decryptOutput = encryptionSdk.Decrypt(decryptInput);
```

AWS Encryption CLI

To decrypt in discovery mode, use the **discovery** attribute of the `--wrapping-keys` parameter. The **discovery-account** and **discovery-partition** attributes create a discovery filter that is optional, but recommended.

To specify the Region, this command includes the **region** attribute of the `--wrapping-keys` parameter.

```
# Decrypt in discovery mode with a multi-Region KMS key

$ aws-encryption-cli --decrypt \
    --input hello.txt.encrypted \
    --wrapping-keys discovery=true \
        discovery-account=111122223333 \
        discovery-partition=aws \
        region=us-west-2 \
    --encryption-context purpose=test \
    --metadata-output ~/metadata \
    --max-encrypted-data-keys 1 \
    --buffer \
    --output .
```

Java

To specify the local Region, use the `builder().withDiscoveryMrkRegion` parameter. Otherwise, the AWS Encryption SDK gets the local Region from the Region configured in the [AWS SDK for Java](#).

For a complete example, see [DiscoveryMultiRegionDecryptionExample.java](#) in the AWS Encryption SDK for Java repository on GitHub.

```
// Decrypt in discovery mode with a multi-Region KMS key

// Instantiate the client
final AwsCrypto crypto = AwsCrypto.builder()
    .withCommitmentPolicy(CommitmentPolicy.RequireEncryptRequireDecrypt)
    .build();

DiscoveryFilter discoveryFilter = new DiscoveryFilter("aws", 111122223333);

AwsKmsMrkAwareMasterKeyProvider mrkDiscoveryProvider = AwsKmsMrkAwareMasterKeyProvider
    .builder()
    .withDiscoveryMrkRegion(Region.US_WEST_2)
    .buildDiscovery(discoveryFilter);

// Decrypt your ciphertext
final CryptoResult<byte[], AwsKmsMrkAwareMasterKey> decryptResult = crypto
    .decryptData(mrkDiscoveryProvider, ciphertext);
```

JavaScript Browser

To decrypt in discovery mode with a symmetric multi-Region key, use the `AwsKmsMrkAwareSymmetricDiscoveryKeyringBrowser()` method.

For a complete example, see [kms_multi_region_discovery.ts](#) in the AWS Encryption SDK for JavaScript repository on GitHub.

```
/* Decrypt in discovery mode with a multi-Region KMS key */

import {
  AwsKmsMrkAwareSymmetricDiscoveryKeyringBrowser,
  buildClient,
  CommitmentPolicy,
  KMS,
} from '@aws-crypto/client-browser'

/* Instantiate an AWS Encryption SDK client */
const { decrypt } = buildClient()

declare const credentials: {
  accessKeyId: string
  secretAccessKey: string
  sessionToken: string
}

/* Instantiate the KMS client with an explicit Region */
const client = new KMS({ region: 'us-west-2', credentials })

/* Create a discovery filter */
const discoveryFilter = { partition: 'aws', accountIDs: ['111122223333'] }

/* Create an AWS KMS discovery keyring */
const mrkDiscoveryKeyring = new AwsKmsMrkAwareSymmetricDiscoveryKeyringBrowser({
  client,
  discoveryFilter,
})

/* Decrypt the data */
const { plaintext, messageHeader } = await decrypt(mrkDiscoveryKeyring, ciphertext)
```

JavaScript Node.js

To decrypt in discovery mode with a symmetric multi-Region key, use the `AwsKmsMrkAwareSymmetricDiscoveryKeyringNode()` method.

For a complete example, see [kms_multi_region_discovery.ts](#) in the AWS Encryption SDK for JavaScript repository on GitHub.

```
/* Decrypt in discovery mode with a multi-Region KMS key */

import {
  AwsKmsMrkAwareSymmetricDiscoveryKeyringNode,
  buildClient,
  CommitmentPolicy,
  KMS,
} from '@aws-crypto/client-node'

/* Instantiate the Encryption SDK client
const { decrypt } = buildClient()

/* Instantiate the KMS client with an explicit Region */
const client = new KMS({ region: 'us-west-2' })

/* Create a discovery filter */
const discoveryFilter = { partition: 'aws', accountIDs: ['111122223333'] }

/* Create an AWS KMS discovery keyring */
```

```
const mrkDiscoveryKeyring = new AwsKmsMrkAwareSymmetricDiscoveryKeyringNode({
  client,
  discoveryFilter,
})

/* Decrypt your ciphertext */
const { plaintext, messageHeader } = await decrypt(mrkDiscoveryKeyring, result)
```

Python

To decrypt in discovery mode with a multi-Region key, use the `MRKAwareDiscoveryAwsKmsMasterKeyProvider()` method.

For a complete example, see [mrk_aware_kms_provider.py](#) in the AWS Encryption SDK for Python repository on GitHub.

```
# Decrypt in discovery mode with a multi-Region KMS key

# Instantiate the client
client = aws_encryption_sdk.EncryptionSDKClient()

# Create the discovery filter and specify the region
decrypt_kwargs = dict(
    discovery_filter=DiscoveryFilter(account_ids="111122223333", partition="aws"),
    discovery_region="us-west-2",
)

# Use the multi-Region method to create the master key provider
# in discovery mode
mrk_discovery_key_provider = MRKAwareDiscoveryAwsKmsMasterKeyProvider(**decrypt_kwargs)

# Decrypt your ciphertext
plaintext, _ = client.decrypt(
    source=ciphertext,
    key_provider=mrk_discovery_key_provider
)
```

Choosing an algorithm suite

The AWS Encryption SDK supports several [symmetric and asymmetric encryption algorithms \(p. 9\)](#) for encrypting your data keys under the wrapping keys you specify. However, when it uses those data keys to encrypt your data, the AWS Encryption SDK defaults to a [recommended algorithm suite \(p. 14\)](#) that uses the AES-GCM algorithm with [key derivation \(p. 224\)](#), [digital signatures \(p. 12\)](#), and [key commitment \(p. 10\)](#). Although the default algorithm suite is likely to be suitable for most applications, you can choose an alternate algorithm suite. For example, some trust models would be satisfied by an algorithm suite without [digital signatures \(p. 12\)](#). For information about the algorithm suites that the AWS Encryption SDK supports, see [Supported algorithm suites in the AWS Encryption SDK \(p. 13\)](#).

The following examples show you how to select an alternate algorithm suite when encrypting. These examples select a recommended AES-GCM algorithm suite with key derivation and key commitment, but without digital signatures. When you encrypt with an algorithm suite that does not include digital signatures, use the unsigned-only decryption mode when decrypting. This mode, which fails if it encounters a signed ciphertext, is most useful when streaming decryption.

C

To specify an alternate algorithm suite in the AWS Encryption SDK for C, you must create a CMM explicitly. Then use the `aws_cryptosdk_default_cmm_set_alg_id` with the CMM and the selected algorithm suite.

```
/* Specify an algorithm suite without signing */

/* Load error strings for debugging */
aws_cryptosdk_load_error_strings();

/* Construct an AWS KMS keyring */
struct aws_cryptosdk_keyring *kms_keyring =
    Aws::Cryptosdk::KmsKeyring::Builder().Build(key_arn);

/* To set an alternate algorithm suite, create an cryptographic
   materials manager (CMM) explicitly
   */
struct aws_cryptosdk_cmm *cmm = aws_cryptosdk_default_cmm_new(aws_default_allocator(),
    kms_keyring);
aws_cryptosdk_keyring_release(kms_keyring);

/* Specify the algorithm suite for the CMM */
aws_cryptosdk_default_cmm_set_alg_id(cmm, ALG_AES256_GCM_HKDF_SHA512_COMMIT_KEY);

/* Construct the session with the CMM,
   then release the CMM reference
   */
struct aws_cryptosdk_session *session = aws_cryptosdk_session_new_from_cmm_2(alloc,
    AWS_CRYPTOSDK_ENCRYPT, cmm);
aws_cryptosdk_cmm_release(cmm);

/* Encrypt the data
   Use aws_cryptosdk_session_process_full with non-streaming data
   */
if (AWS_OP_SUCCESS != aws_cryptosdk_session_process_full(
    session,
    ciphertext,
    ciphertext_buf_sz,
    &ciphertext_len,
    plaintext,
    plaintext_len)) {
    aws_cryptosdk_session_destroy(session);
    return AWS_OP_ERR;
}
```

When decrypting data that was encrypted without digital signatures, use `AWS_CRYPTOSDK_DECRYPT_UNSIGNED`. This causes the decrypt to fail if it encounters signed ciphertext.

```
/* Decrypt unsigned streaming data */

/* Load error strings for debugging */
aws_cryptosdk_load_error_strings();

/* Construct an AWS KMS keyring */
struct aws_cryptosdk_keyring *kms_keyring =
    Aws::Cryptosdk::KmsKeyring::Builder().Build(key_arn);

/* Create a session for decrypting with the AWS KMS keyring
   Then release the keyring reference
   */
struct aws_cryptosdk_session *session =
    aws_cryptosdk_session_new_from_keyring_2(alloc, AWS_CRYPTOSDK_DECRYPT_UNSIGNED,
    kms_keyring);
aws_cryptosdk_keyring_release(kms_keyring);

if (!session) {
    return AWS_OP_ERR;
}
```

```
/* Limit encrypted data keys */
aws_cryptosdk_session_set_max_encrypted_data_keys(session, 1);

/* Decrypt
Use aws_cryptosdk_session_process_full with non-streaming data
*/
if (AWS_OP_SUCCESS != aws_cryptosdk_session_process_full(
    session,
    plaintext,
    plaintext_buf_sz,
    &plaintext_len,
    ciphertext,
    ciphertext_len)) {
    aws_cryptosdk_session_destroy(session);
    return AWS_OP_ERR;
}
```

C# / .NET

To specify an alternate algorithm suite in the AWS Encryption SDK for .NET, specify the `AlgorithmSuiteId` property of an [EncryptInput](#) object. The AWS Encryption SDK for .NET includes [constants](#) that you can use to identify your preferred algorithm suite.

The AWS Encryption SDK for .NET doesn't have a method to detect signed ciphertext when streaming decryption because this library doesn't support streaming data.

```
// Specify an algorithm suite without signing

// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

// Create the keyring
var keyringInput = new CreateAwsKmsKeyringInput
{
    KmsClient = new AmazonKeyManagementServiceClient(),
    KmsKeyId = keyArn
};
var keyring = materialProviders.CreateAwsKmsKeyring(keyringInput);

// Encrypt your plaintext data
var encryptInput = new EncryptInput
{
    Plaintext = plaintext,
    Keyring = keyring,
    AlgorithmSuiteId = AlgorithmSuiteId.ALG_AES_256_GCM_HKDF_SHA512_COMMIT_KEY
};
var encryptOutput = encryptionSdk.Encrypt(encryptInput);
```

AWS Encryption CLI

When encrypting the `hello.txt` file, this example uses the `--algorithm` parameter to specify an algorithm suite without digital signatures.

```
# Specify an algorithm suite without signing

# To run this example, replace the fictitious key ARN with a valid value.
$ keyArn=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab
```

```
$ aws-encryption-cli --encrypt \  
  --input hello.txt \  
  --wrapping-keys key=$keyArn \  
  --algorithm AES_256_GCM_HKDF_SHA512_COMMIT_KEY \  
  --metadata-output ~/metadata \  
  --encryption-context purpose=test \  
  --commitment-policy require-encrypt-require-decrypt \  
  --output hello.txt.encrypted \  
  --decode
```

When decrypting, this example uses the `--decrypt-unsigned` parameter. This parameter is recommended to ensure that you are decrypting unsigned ciphertext, especially with the CLI, which is always streaming input and output.

```
# Decrypt unsigned streaming data  
  
# To run this example, replace the fictitious key ARN with a valid value.  
$ keyArn=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab  
  
$ aws-encryption-cli --decrypt-unsigned \  
  --input hello.txt.encrypted \  
  --wrapping-keys key=$keyArn \  
  --max-encrypted-data-keys 1 \  
  --commitment-policy require-encrypt-require-decrypt \  
  --encryption-context purpose=test \  
  --metadata-output ~/metadata \  
  --output .
```

Java

To specify an alternate algorithm suite, use the `AwsCrypto.builder().withEncryptionAlgorithm()` method. This example specifies an alternate algorithm suite without digital signatures.

```
// Specify an algorithm suite without signing  
  
// Instantiate the client  
AwsCrypto crypto = AwsCrypto.builder()  
    .withCommitmentPolicy(CommitmentPolicy.RequireEncryptRequireDecrypt)  
    .withEncryptionAlgorithm(CryptoAlgorithm.ALG_AES_256_GCM_HKDF_SHA512_COMMIT_KEY)  
    .build();  
  
String awsKmsKey = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
// Create a master key provider in strict mode  
KmsMasterKeyProvider masterKeyProvider = KmsMasterKeyProvider.builder()  
    .buildStrict(awsKmsKey);  
  
// Create an encryption context to identify this ciphertext  
Map<String, String> encryptionContext = Collections.singletonMap("Example",  
    "FileStreaming");  
  
// Encrypt your plaintext data  
CryptoResult<byte[], KmsMasterKey> encryptResult = crypto.encryptData(  
    masterKeyProvider,  
    sourcePlaintext,  
    encryptionContext);  
byte[] ciphertext = encryptResult.getResult();
```

When streaming data for decryption, use the `createUnsignedMessageDecryptingStream()` method to ensure that all ciphertext that you're decrypting is unsigned.

```
// Decrypt unsigned streaming data

// Instantiate the client
AwsCrypto crypto = AwsCrypto.builder()
    .withCommitmentPolicy(CommitmentPolicy.RequireEncryptRequireDecrypt)
    .withMaxEncryptedDataKeys(1)
    .build();

// Create a master key provider in strict mode
String awsKmsKey = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
KmsMasterKeyProvider masterKeyProvider = KmsMasterKeyProvider.builder()
    .buildStrict(awsKmsKey);

// Decrypt the encrypted message
FileInputStream in = new FileInputStream(srcFile + ".encrypted");
CryptoInputStream<KmsMasterKey> decryptingStream =
    crypto.createUnsignedMessageDecryptingStream(masterKeyProvider, in);

// Return the plaintext data
// Write the plaintext data to disk
FileOutputStream out = new FileOutputStream(srcFile + ".decrypted");
IOUtils.copy(decryptingStream, out);
decryptingStream.close();
```

JavaScript Browser

To specify an alternate algorithm suite, use the `suiteId` parameter with an `AlgorithmSuiteIdentifier` enum value.

```
// Specify an algorithm suite without signing

// Instantiate the client
const { encrypt } = buildClient( CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT )

// Specify a KMS key
const generatorKeyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

// Create a keyring with the KMS key
const keyring = new KmsKeyringBrowser({ generatorKeyId })

// Encrypt your plaintext data
const { result } = await encrypt(keyring, cleartext, { suiteId:
    AlgorithmSuiteIdentifier.ALG_AES256_GCM_IV12_TAG16_HKDF_SHA512_COMMIT_KEY,
    encryptionContext: context, })
```

When decrypting, use the standard `decrypt` method. AWS Encryption SDK for JavaScript in the browser doesn't have a `decrypt-unsigned` mode because the browser doesn't support streaming.

```
// Decrypt unsigned streaming data

// Instantiate the client
const { decrypt } = buildClient( CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT )

// Create a keyring with the same KMS key used to encrypt
const generatorKeyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
const keyring = new KmsKeyringBrowser({ generatorKeyId })

// Decrypt the encrypted message
const { plaintext, messageHeader } = await decrypt(keyring, ciphertextMessage)
```

JavaScript Node.js

To specify an alternate algorithm suite, use the `suiteId` parameter with an `AlgorithmSuiteIdentifier` enum value.

```
// Specify an algorithm suite without signing

// Instantiate the client
const { encrypt } = buildClient( CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT )

// Specify a KMS key
const generatorKeyId = "arn:aws:kms:us-west-2:11112223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

// Create a keyring with the KMS key
const keyring = new KmsKeyringNode({ generatorKeyId })

// Encrypt your plaintext data
const { result } = await encrypt(keyring, cleartext, { suiteId:
  AlgorithmSuiteIdentifier.ALG_AES256_GCM_IV12_TAG16_HKDF_SHA512_COMMIT_KEY,
  encryptionContext: context, })
```

When decrypting data that was encrypted without digital signatures, use `decryptUnsignedMessageStream`. This method fails if it encounters signed ciphertext.

```
// Decrypt unsigned streaming data

// Instantiate the client
const { decryptUnsignedMessageStream } =
  buildClient( CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT )

// Create a keyring with the same KMS key used to encrypt
const generatorKeyId = "arn:aws:kms:us-west-2:11112223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
const keyring = new KmsKeyringNode({ generatorKeyId })

// Decrypt the encrypted message
const outputStream =
  createReadStream(filename) .pipe(decryptUnsignedMessageStream(keyring))
```

Python

To specify an alternate encryption algorithm, use the `algorithm` parameter with an `Algorithm` enum value.

```
# Specify an algorithm suite without signing

# Instantiate a client
client =
  aws_encryption_sdk.EncryptionSDKClient(commitment_policy=CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT,
                                         max_encrypted_data_keys=1)

# Create a master key provider in strict mode
aws_kms_key = "arn:aws:kms:us-west-2:11112223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
aws_kms_strict_master_key_provider = StrictAwsKmsMasterKeyProvider(
    key_ids=[aws_kms_key]
)

# Encrypt the plaintext using an alternate algorithm suite
ciphertext, encrypted_message_header = client.encrypt(
```

```
        algorithm=Algorithm.AES_256_GCM_HKDF_SHA512_COMMIT_KEY, source=source_plaintext,  
        key_provider=kms_key_provider  
    )
```

When decrypting messages that were encrypted without digital signatures, use the decrypt-unsigned streaming mode, especially when decrypting while streaming.

```
# Decrypt unsigned streaming data  
  
# Instantiate the client  
client =  
    aws_encryption_sdk.EncryptionSDKClient(commitment_policy=CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_  
                                           max_encrypted_data_keys=1)  
  
# Create a master key provider in strict mode  
aws_kms_key = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"  
aws_kms_strict_master_key_provider = StrictAwsKmsMasterKeyProvider(  
    key_ids=[aws_kms_key]  
)  
  
# Decrypt with decrypt-unsigned  
with open(ciphertext_filename, "rb") as ciphertext, open(cycled_plaintext_filename,  
    "wb") as plaintext:  
    with client.stream(mode="decrypt-unsigned",  
        source=ciphertext,  
        key_provider=master_key_provider) as decryptor:  
        for chunk in decryptor:  
            plaintext.write(chunk)  
  
# Verify that the encryption context  
assert all(  
    pair in decryptor.header.encryption_context.items() for pair in  
    encryptor.header.encryption_context.items()  
)  
return ciphertext_filename, cycled_plaintext_filename
```

Limit encrypted data keys

You can limit the number of encrypted data keys in an encrypted message. This best practice feature can help you detect a misconfigured keyring when encrypting or a malicious ciphertext when decrypting. It also prevents unnecessary, expensive, and potentially exhaustive calls to your key infrastructure. Limiting encrypted data keys is most valuable when you are decrypting messages from an untrusted source.

Although most encrypted messages have one encrypted data key for each wrapping key used in the encryption, an encrypted message can contain up to 65,535 encrypted data keys. A malicious actor might construct an encrypted message with thousands of encrypted data keys, none of which can be decrypted. As a result, the AWS Encryption SDK would attempt to decrypt each encrypted data key until it exhausted the encrypted data keys in the message.

To limit encrypted data keys, use the `MaxEncryptedDataKeys` parameter. This parameter is available for all supported programming languages beginning in versions 1.9.x and 2.2.x of the AWS Encryption SDK. It is optional and valid when encrypting and decrypting. The following examples decrypt data that was encrypted under three different wrapping keys. The `MaxEncryptedDataKeys` value is set to 3.

C

```
/* Load error strings for debugging */
```

```
aws_cryptosdk_load_error_strings();

/* Construct an AWS KMS keyring */
struct aws_cryptosdk_keyring *kms_keyring =
    Aws::Cryptosdk::KmsKeyring::Builder().Build(key_arn1, { key_arn2, key_arn3 });

/* Create a session */
struct aws_cryptosdk_session *session =
    aws_cryptosdk_session_new_from_keyring_2(alloc, AWS_CRYPTOSDK_DECRYPT,
    kms_keyring);
aws_cryptosdk_keyring_release(kms_keyring);

/* Limit encrypted data keys */
aws_cryptosdk_session_set_max_encrypted_data_keys(session, 3);

/* Decrypt */
size_t ciphertext_consumed_output;
aws_cryptosdk_session_process(session,
    plaintext_output,
    plaintext_buf_sz_output,
    &plaintext_len_output,
    ciphertext_input,
    ciphertext_len_input,
    &ciphertext_consumed_output);
assert(aws_cryptosdk_session_is_done(session));
assert(ciphertext_consumed == ciphertext_len);
```

C# / .NET

To limit encrypted data keys in the AWS Encryption SDK for .NET, instantiate a client for the AWS Encryption SDK for .NET and set its optional `MaxEncryptedDataKeys` parameter to the desired value. Then, call the `Decrypt()` method on the configured AWS Encryption SDK instance.

```
// Decrypt with limited data keys

// Instantiate the material providers
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

// Configure the commitment policy on the AWS Encryption SDK instance
var config = new AwsEncryptionSdkConfig
{
    MaxEncryptedDataKeys = 3
};
var encryptionSdk = AwsEncryptionSdkFactory.CreateAwsEncryptionSdk(config);

// Create the keyring
string keyArn = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
var createKeyringInput = new CreateAwsKmsKeyringInput
{
    KmsClient = new AmazonKeyManagementServiceClient(),
    KmsKeyId = keyArn
};
var decryptKeyring = materialProviders.CreateAwsKmsKeyring(createKeyringInput);

// Decrypt the ciphertext
var decryptInput = new DecryptInput
{
    Ciphertext = ciphertext,
    Keyring = decryptKeyring
};
var decryptOutput = encryptionSdk.Decrypt(decryptInput);
```

AWS Encryption CLI

```
# Decrypt with limited encrypted data keys

$ aws-encryption-cli --decrypt \
  --input hello.txt.encrypted \
  --wrapping-keys key=$key_arn1 key=$key_arn2 key=$key_arn3 \
  --buffer \
  --max-encrypted-data-keys 3 \
  --encryption-context purpose=test \
  --metadata-output ~/metadata \
  --output .
```

Java

```
// Construct a client with limited encrypted data keys
final AwsCrypto crypto = AwsCrypto.builder()
    .withMaxEncryptedDataKeys(3)
    .build();

// Create an AWS KMS master key provider
final KmsMasterKeyProvider keyProvider = KmsMasterKeyProvider.builder()
    .buildStrict(keyArn1, keyArn2, keyArn3);

// Decrypt
final CryptoResult<byte[], KmsMasterKey> decryptResult =
    crypto.decryptData(keyProvider, ciphertext)
```

JavaScript Browser

```
// Construct a client with limited encrypted data keys
const { encrypt, decrypt } = buildClient({ maxEncryptedDataKeys: 3 })

declare const credentials: {
  accessKeyId: string
  secretAccessKey: string
  sessionToken: string
}
const clientProvider = getClient(KMS, {
  credentials: { accessKeyId, secretAccessKey, sessionToken }
})

// Create an AWS KMS keyring
const keyring = new KmsKeyringBrowser({
  clientProvider,
  keyIds: [keyArn1, keyArn2, keyArn3],
})

// Decrypt
const { plaintext, messageHeader } = await decrypt(keyring, ciphertext)
```

JavaScript Node.js

```
// Construct a client with limited encrypted data keys
const { encrypt, decrypt } = buildClient({ maxEncryptedDataKeys: 3 })

// Create an AWS KMS keyring
const keyring = new KmsKeyringBrowser({
  keyIds: [keyArn1, keyArn2, keyArn3],
})

// Decrypt
```

```
const { plaintext, messageHeader } = await decrypt(keyring, ciphertext)
```

Python

```
# Instantiate a client with limited encrypted data keys
client = aws_encryption_sdk.EncryptionSDKClient(max_encrypted_data_keys=3)

# Create an AWS KMS master key provider
master_key_provider = aws_encryption_sdk.StrictAwsKmsMasterKeyProvider(
    key_ids=[key_arn1, key_arn2, key_arn3])

# Decrypt
plaintext, header = client.decrypt(source=ciphertext, key_provider=master_key_provider)
```

Work with streaming data

When you stream data for decryption, be aware that the AWS Encryption SDK returns decrypted plaintext after the integrity checks are complete, but before the digital signature is verified. To ensure that you don't return or use plaintext until the signature is verified, we recommend that you buffer the streamed plaintext until the entire decryption process is complete.

This issue arises only when you are streaming ciphertext for decryption, and only when you are using an algorithm suite, such as the [default algorithm suite \(p. 13\)](#), that includes [digital signatures \(p. 12\)](#).

To make the buffering easier, some AWS Encryption SDK language implementations, such as AWS Encryption SDK for JavaScript in Node.js, include a buffering feature as part of the decrypt method. The AWS Encryption CLI, which always streams input and output introduced a `--buffer` parameter in versions 1.9.x and 2.2.x. In other language implementations, you can use existing buffering features. (The AWS Encryption SDK for .NET does not support streaming.)

If you are using an algorithm suite without digital signatures, be sure to use the `decrypt-unsigned` feature in each language implementation. This feature decrypts ciphertext but fails if it encounters signed ciphertext. For details, see [Choosing an algorithm suite \(p. 35\)](#).

Cache data keys

In general, reusing data keys is discouraged, but the AWS Encryption SDK offers a [data key caching \(p. 152\)](#) option that provides limited reuse of data keys. Data key caching can improve the performance of some applications and reduce calls to your key infrastructure. Before using data key caching in production, adjust the [security thresholds \(p. 168\)](#), and test to make sure that the benefits outweigh the disadvantages of reusing data keys.

Using keyrings

The AWS Encryption SDK for C, the AWS Encryption SDK for JavaScript, and the AWS Encryption SDK for .NET use *keyrings* to perform [envelope encryption](#). Keyrings generate, encrypt, and decrypt data keys. Keyrings determine the source of the unique data keys that protect each message, and the [wrapping keys](#) (p. 7) that encrypt that data key. You specify a keyring when encrypting and the same or a different keyring when decrypting. You can use the keyrings that the SDK provides or write your own compatible custom keyrings.

You can use each keyring individually or combine keyrings into a [multi-keyring](#) (p. 64). Although most keyrings can generate, encrypt, and decrypt data keys, you might create a keyring that performs only one particular operation, such as a keyring that only generates data keys, and use that keyring in combination with others.

We recommend that you use a keyring that protects your wrapping keys and performs cryptographic operations within a secure boundary, such as the AWS KMS keyring, which uses AWS KMS keys that never leave [AWS Key Management Service](#) (AWS KMS) unencrypted. You can also write a keyring that uses wrapping keys that are stored in your hardware security modules (HSMs) or protected by other master key services. For details, see the [Keyring Interface](#) topic in the *AWS Encryption SDK Specification*.

Keyrings play the role of [master keys](#) (p. 7) and [master key providers](#) (p. 7) in the AWS Encryption SDK for Java, AWS Encryption SDK for Python, and the AWS Encryption CLI. If you use different language implementations of the AWS Encryption SDK to encrypt and decrypt your data, be sure to use compatible keyrings and master key providers. For details, see [Keyring compatibility](#) (p. 47).

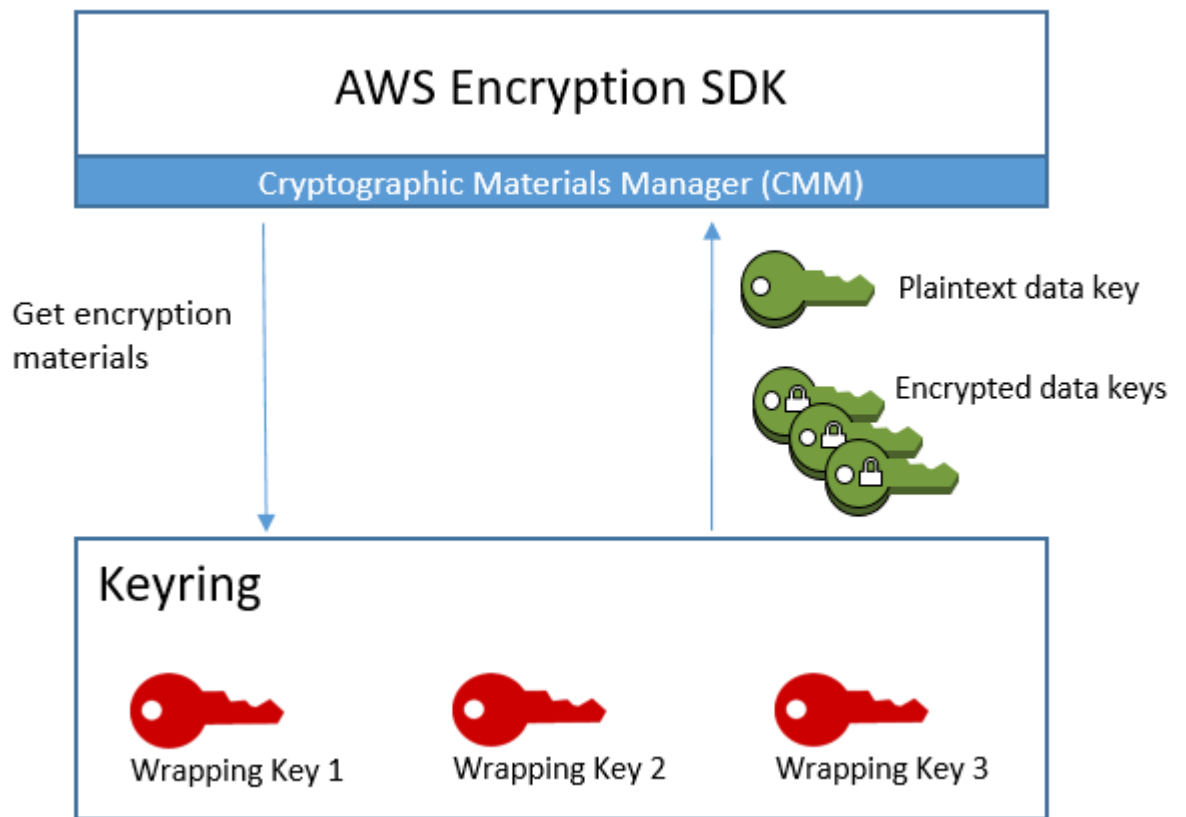

This topic explains how to use the keyring feature of the AWS Encryption SDK and how to choose a keyring. For examples of creating and using keyrings, see the [C](#) (p. 68) and [JavaScript](#) (p. 95) topics.

Topics

- [How keyrings work](#) (p. 45)
- [Keyring compatibility](#) (p. 47)
- [Choosing a keyring](#) (p. 48)

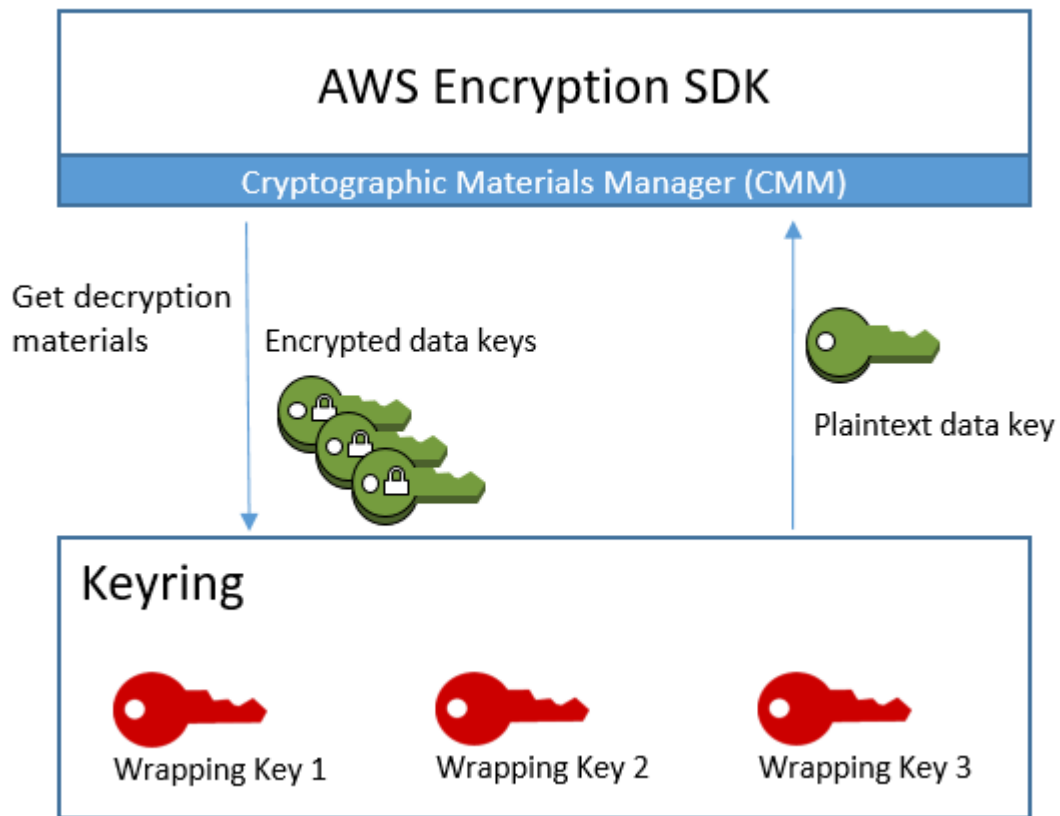

How keyrings work

When you encrypt data, the AWS Encryption SDK asks the keyring for encryption materials. The keyring returns a plaintext data key and a copy of the data key that's encrypted by each of the wrapping keys in the keyring. The AWS Encryption SDK uses the plaintext key to encrypt the data, and then destroys the plaintext data key. Then, the AWS Encryption SDK returns an [encrypted message](#) (p. 8) that includes the encrypted data keys and the encrypted data.

When you decrypt data, you can use the same keyring that you used to encrypt the data, or a different one. To decrypt the data, a decryption keyring must include (or have access to) at least one wrapping key in the encryption keyring.

The AWS Encryption SDK passes the encrypted data keys from the encrypted message to the keyring, and asks the keyring to decrypt any one of them. The keyring uses its wrapping keys to decrypt one of the encrypted data keys and returns a plaintext data key. The AWS Encryption SDK uses the plaintext data key to decrypt the data. If none of the wrapping keys in the keyring can decrypt any of the encrypted data keys, the decrypt operation fails.

You can use a single keyring or also combine keyrings of the same type or a different type into a [multi-keyring](#) (p. 64). When you encrypt data, the multi-keyring returns a copy of the data key encrypted by all of the wrapping keys in all of the keyrings that comprise the multi-keyring. You can decrypt the data using a keyring with any one of the wrapping keys in the multi-keyring.

Keyring compatibility

Although the different language implementations of the AWS Encryption SDK have some architectural differences, they are fully compatible, subject to language constraints. You can encrypt your data using one language implementation and decrypt it with any other language implementation. However, you must use the same or corresponding wrapping keys to encrypt and decrypt your data keys. For information about language constraints, see the topic about each language implementation, such as [the section called "Compatibility"](#) (p. 95) in the AWS Encryption SDK for JavaScript topic.

Varying requirements for encryption keyrings

In AWS Encryption SDK language implementations other than the AWS Encryption SDK for C, all wrapping keys in an encryption keyring (or multi-keyring) or master key provider must be able to encrypt the data key. If any wrapping key fails to encrypt, the encrypt method fails. As a result, the caller must have the [required permissions](#) (p. 49) for all keys in the keyring. If you use a discovery keyring to encrypt data, alone or in a multi-keyring, the encrypt operation fails.

The exception is the AWS Encryption SDK for C, where the encrypt operation ignores a standard discovery keyring, but fails if you specify a multi-Region discovery keyring, alone or in a multi-keyring.

Compatible Keyrings and Master Key Providers

The following table shows which master keys and master key providers are compatible with the keyrings that the AWS Encryption SDK supplies. Any minor incompatibility due to language constraints is explained in the topic about the language implementation.

Keyring:	Master Key Provider:
AWS KMS keyring (p. 49)	KMSMasterKey (Java) KMSMasterKeyProvider (Java) KMSMasterKey (Python) KMSMasterKeyProvider (Python) Note The AWS Encryption SDK for Python and AWS Encryption SDK for Java don't include a master key or master key provider that is equivalent to the AWS KMS regional discovery keyring (p. 56) .
Raw AES keyring (p. 59)	When they are used with symmetric encryption keys: JceMasterKey (Java) RawMasterKey (Python)
Raw RSA keyring (p. 61)	When they are used with asymmetric encryption keys: JceMasterKey (Java) RawMasterKey (Python) Note The AWS Encryption SDK does not support asymmetric AWS KMS keys.

Choosing a keyring

Your keyring determines the wrapping keys that protect your data keys, and ultimately, your data. Use the most secure wrapping keys that are practical for your task. Whenever possible use wrapping keys that are protected by a hardware security module or a key management infrastructure, such as KMS keys in [AWS Key Management Service \(AWS KMS\)](#) or encryption keys [AWS CloudHSM](#).

The AWS Encryption SDK provides several keyrings and keyring configurations in multiple programming languages, and you can create your own custom keyrings. You can also create a [multi-keyring \(p. 64\)](#) that includes one or more keyrings of the same or a different type.

Topics

- [AWS KMS keyrings \(p. 49\)](#)
- [Raw AES keyrings \(p. 59\)](#)
- [Raw RSA keyrings \(p. 61\)](#)
- [Multi-keyrings \(p. 64\)](#)

AWS KMS keyrings

An AWS KMS keyring uses symmetric encryption [AWS KMS keys](#) to generate, encrypt, and decrypt data keys. AWS Key Management Service (AWS KMS) protects your KMS keys and performs cryptographic operations within the FIPS boundary. We recommend that you use a AWS KMS keyring, or a keyring with similar security properties, whenever possible.

You can use an AWS KMS multi-Region key in an AWS KMS keyring or master key provider beginning in [version 2.3.x \(p. 199\)](#) of the AWS Encryption SDK and [version 3.0.x \(p. 199\)](#) of the AWS Encryption CLI. For details and examples of using the new multi-Region-aware symbol, see [Use multi-Region AWS KMS keys \(p. 21\)](#). For information about multi-Region keys, see [Using multi-Region keys](#) in the *AWS Key Management Service Developer Guide*.

Note

The AWS Encryption SDK does not support asymmetric KMS keys. If you include an asymmetric KMS key in an encryption keyring, the encrypt call fails. If you include it in a decryption keyring, it is ignored.

All mentions of *KMS keyrings* in the AWS Encryption SDK refer to AWS KMS keyrings.

AWS KMS keyrings can include two types of wrapping keys:

- **Generator key:** Generates a plaintext data key and encrypts it. A keyring that encrypts data must have one generator key.
- **Additional keys:** Encrypts the plaintext data key that the generator key generated. AWS KMS keyrings can have zero or more additional keys.

When encrypting, the AWS KMS keyring that you use must have a generator key. When decrypting, the generator key is optional, and the distinction between generators keys and additional keys is ignored.

When an AWS KMS encryption keyring has just one AWS KMS key, that key is used to generate and encrypt the data key.

Like all keyrings, AWS KMS keyrings can be used independently or in a [multi-keyring \(p. 64\)](#) with other keyrings of the same or a different type.

Topics

- [Required permissions for AWS KMS keyrings \(p. 49\)](#)
- [Identifying AWS KMS keys in an AWS KMS keyring \(p. 50\)](#)
- [Creating an AWS KMS keyring for encryption \(p. 50\)](#)
- [Creating an AWS KMS keyring for decryption \(p. 52\)](#)
- [Using an AWS KMS discovery keyring \(p. 55\)](#)
- [Using an AWS KMS regional discovery keyring \(p. 56\)](#)

Required permissions for AWS KMS keyrings

The AWS Encryption SDK doesn't require an AWS account and it doesn't depend on any AWS service. However, to use an AWS KMS keyring, you need an AWS account and the following minimum permissions on the AWS KMS keys in your keyring.

- To encrypt with an AWS KMS keyring, you need [kms:GenerateDataKey](#) permission on the generator key. You need [kms:Encrypt](#) permission on all additional keys in the AWS KMS keyring.
- To decrypt with an AWS KMS keyring, you need [kms:Decrypt](#) permission on at least one key in the AWS KMS keyring.

- To encrypt with a multi-keyring comprised of AWS KMS keyrings, you need [kms:GenerateDataKey](#) permission on the generator key in the generator keyring. You need [kms:Encrypt](#) permission on all other keys in all other AWS KMS keyrings.

For detailed information about permissions for AWS KMS keys, see [Authentication and access control](#) in the *AWS Key Management Service Developer Guide*.

Identifying AWS KMS keys in an AWS KMS keyring

An AWS KMS keyring can include one or more AWS KMS keys. To specify an AWS KMS key in an AWS KMS keyring, use a supported AWS KMS key identifier. The key identifiers you can use to identify an AWS KMS key in a keyring vary with the operation and the language implementation. For details about the key identifiers for an AWS KMS key, see [Key Identifiers](#) in the *AWS Key Management Service Developer Guide*.

As a best practice, use the most specific key identifier that is practical for your task.

- In an encryption keyring for the AWS Encryption SDK for C, you can use a [key ARN](#) or [alias ARN](#) to identify KMS keys. In all other language implementations, you can use a [key ID](#), [key ARN](#), [alias name](#), or [alias ARN](#) to encrypt data.
- In a decryption keyring, you must use a key ARN to identify AWS KMS keys. This requirement applies to all language implementations of the AWS Encryption SDK. For details, see [Select wrapping keys \(p. 20\)](#).
- In a keyring used for encryption and decryption, you must use a key ARN to identify AWS KMS keys. This requirement applies to all language implementations of the AWS Encryption SDK.

If you specify an alias name or alias ARN for a KMS key in an encryption keyring, the encrypt operation saves the key ARN currently associated with the alias in the metadata of the encrypted data key. It does not save the alias. Changes to the alias don't affect the KMS key used to decrypt your encrypted data keys.

Creating an AWS KMS keyring for encryption

You can configure each AWS KMS keyring with a single AWS KMS key or multiple AWS KMS keys in the same or different AWS accounts and AWS Regions. The AWS KMS keys must be symmetric encryption keys (SYMMETRIC_DEFAULT). You can also use a symmetric encryption [multi-Region KMS key \(p. 21\)](#). As with all keyrings, you can use one or more AWS KMS keyrings in a [multi-keyring \(p. 64\)](#).

When you create an AWS KMS keyring to encrypt data, you must specify a *generator key*, which is an AWS KMS key that is used to generate a plaintext data key and encrypt it. The data key is mathematically unrelated to the KMS key. Then, if you choose, you can specify additional AWS KMS keys that encrypt the same plaintext data key.

To decrypt the encrypted message protected by this keyring, the keyring that you use must include at least one of the AWS KMS keys defined in the keyring, or no AWS KMS keys. (An AWS KMS keyring with no AWS KMS keys is known as an [AWS KMS discovery keyring \(p. 55\)](#).)

In AWS Encryption SDK language implementations other than the AWS Encryption SDK for C, all wrapping keys in an encryption keyring or multi-keyring must be able to encrypt the data key. If any wrapping key fails to encrypt, the encrypt method fails. As a result, the caller must have the [required permissions \(p. 49\)](#) for all keys in the keyring. If you use a discovery keyring to encrypt data, alone or in a multi-keyring, the encrypt operation fails. The exception is the AWS Encryption SDK for C, where the encrypt operation ignores a standard discovery keyring, but fails if you specify a multi-Region discovery keyring, alone or in a multi-keyring.

The following examples create an AWS KMS keyring with one generator key and one additional key. These examples use [key ARNs](#) to identify the KMS keys. This is a best practice for AWS KMS keyrings used

for encryption, and a requirement for AWS KMS keyrings used for decryption. For details, see [Identifying AWS KMS keys in an AWS KMS keyring \(p. 50\)](#).

C

To identify an AWS KMS key in an encryption keyring in the AWS Encryption SDK for C, specify a [key ARN](#) or [alias ARN](#). In a decryption keyring, you must use a key ARN. For details, see [Identifying AWS KMS keys in an AWS KMS keyring \(p. 50\)](#).

For a complete example, see [string.cpp](#).

```
const char * generator_key = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"  
  
const char * additional_key = "arn:aws:kms:us-  
west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321"  
  
struct aws_cryptosdk_keyring *kms_encrypt_keyring =  
    Aws::Cryptosdk::KmsKeyring::Builder().Build(generator_key,{additional_key});
```

C# / .NET

To create an AWS KMS keyring with one or multiple AWS KMS keys in the AWS Encryption SDK for .NET, create a multi-keyring. The AWS Encryption SDK for .NET includes a multi-keyring just for AWS KMS keys.

When you specify an AWS KMS key for an encryption keyring in the AWS Encryption SDK for .NET, you can use any valid key identifier: a [key ID](#), [key ARN](#), [alias name](#), or [alias ARN](#). For help identifying the AWS KMS keys in an AWS KMS keyring, see [Identifying AWS KMS keys in an AWS KMS keyring \(p. 50\)](#).

The following example creates an AWS KMS keyring with a generator key and additional keys. For a complete example, see [AwsKmsMultiKeyringExample.cs](#).

```
// Instantiate the AWS Encryption SDK and material provider  
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();  
var materialProviders =  
  
    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();  
  
string generatorKey = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
List<string> additionalKey = new List<string> { "alias/exampleAlias" };  
  
// Instantiate the keyring input object  
var kmsEncryptKeyringInput = new CreateAwsKmsMultiKeyringInput  
{  
    Generator = generatorKey,  
    KmsKeyIds = additionalKey  
};  
  
var kmsEncryptKeyring =  
    materialProviders.CreateAwsKmsMultiKeyring(kmsEncryptKeyringInput);
```

JavaScript Browser

When you specify an AWS KMS key for an encryption keyring in the AWS Encryption SDK for JavaScript, you can use any valid key identifier: a [key ID](#), [key ARN](#), [alias name](#), or [alias ARN](#). For help identifying the AWS KMS keys in an AWS KMS keyring, see [Identifying AWS KMS keys in an AWS KMS keyring \(p. 50\)](#).

For a complete example, see [kms_simple.ts](#) in the AWS Encryption SDK for JavaScript repository in GitHub.

```
const clientProvider = getClient(KMS, { credentials })
const generatorKeyId = 'arn:aws:kms:us-west-2:11112223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'
const additionalKey = 'alias/exampleAlias'

const keyring = new KmsKeyringBrowser({
  clientProvider,
  generatorKeyId,
  keyIds: [additionalKey]
})
```

JavaScript Node.js

When you specify an AWS KMS key for an encryption keyring in the AWS Encryption SDK for JavaScript, you can use any valid key identifier: a [key ID](#), [key ARN](#), [alias name](#), or [alias ARN](#). For help identifying the AWS KMS keys in an AWS KMS keyring, see [Identifying AWS KMS keys in an AWS KMS keyring \(p. 50\)](#).

For a complete example, see [kms_simple.ts](#) in the AWS Encryption SDK for JavaScript repository in GitHub.

```
const generatorKeyId = 'arn:aws:kms:us-west-2:11112223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

const additionalKey = 'alias/exampleAlias'

const keyring = new KmsKeyringNode({
  generatorKeyId,
  keyIds: [additionalKey]
})
```

Creating an AWS KMS keyring for decryption

You also specify an AWS KMS keyring when decrypting the [encrypted message \(p. 8\)](#) that the AWS Encryption SDK returns. If the decryption keyring specifies AWS KMS keys, the AWS Encryption SDK will use only those wrapping keys to decrypt the encrypted data keys in the encrypted message. (You can also use an [AWS KMS discovery keyring \(p. 55\)](#), which doesn't specify any AWS KMS keys.)

When decrypting, the AWS Encryption SDK searches the AWS KMS keyring for an AWS KMS key that can decrypt one of the encrypted data keys. Specifically, the AWS Encryption SDK uses the following pattern for each encrypted data key in an encrypted message.

- The AWS Encryption SDK gets the key ARN of the AWS KMS key that encrypted the data key from the metadata of the encrypted message.
- The AWS Encryption SDK searches the decryption keyring for an AWS KMS key with a matching key ARN.
- If it finds an AWS KMS key with a matching key ARN in the keyring, the AWS Encryption SDK asks AWS KMS to use the KMS key to decrypt the encrypted data key.
- Otherwise, it skips to the next encrypted data key, if any.

The AWS Encryption SDK never attempts to decrypt an encrypted data key unless the key ARN of the AWS KMS key that encrypted that data key is included in the decryption keyring. If the decryption keyring doesn't include the ARNs of any of the AWS KMS keys that encrypted any of the data keys, the AWS Encryption SDK fails the decrypt call without ever calling AWS KMS.

Beginning in [version 1.7.x \(p. 195\)](#), when decrypting an encrypted data key, the AWS Encryption SDK always passes the key ARN of the AWS KMS key to the `KeyId` parameter of the AWS KMS [Decrypt](#) operation. Identifying the AWS KMS key when decrypting is an AWS KMS best practice that assures that you decrypt the encrypted data key with the wrapping key you intend to use.

A decrypt call with an AWS KMS keyring succeeds when at least one AWS KMS key in the decryption keyring can decrypt one of the encrypted data keys in the encrypted message. Also, the caller must have `kms:Decrypt` permission on that AWS KMS key. This behavior enables you to encrypt data under multiple AWS KMS keys in different AWS Regions and accounts, but provide a more limited decryption keyring tailored to a particular account, Region, user, group, or role.

When you specify an AWS KMS key in a decryption keyring, you must use its key ARN. Otherwise, the AWS KMS key is not recognized. For help finding the key ARN, see [Finding the Key ID and ARN](#) in the *AWS Key Management Service Developer Guide*.

Note

If you reuse an encryption keyring for decrypting, be sure that the AWS KMS keys in the keyring are identified by their key ARNs.

For example, the following AWS KMS keyring includes only the additional key that was used in the encryption keyring. However, instead of referring to the additional key by its alias, `exampleAlias`, the example uses the additional key's key ARN as required by decrypt calls.

You can use this keyring to decrypt a message that was encrypted under both the generator key and the additional key, provided that you have permission to use the additional key to decrypt data.

C

```
const char * additional_key = "arn:aws:kms:us-  
west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321"  
  
struct aws_cryptosdk_keyring *kms_decrypt_keyring =  
    Aws::Cryptosdk::KmsKeyring::Builder().Build(additional_key);
```

C# / .NET

Because this decrypt keyring includes only one AWS KMS key, the example uses the `CreateAwsKmsKeyring()` method with an instance of its `CreateAwsKmsKeyringInput` object. To create a AWS KMS keyring with one AWS KMS key, you can use a single-key or multi-key keyring. For details, see [Encrypting data in the AWS Encryption SDK for .NET \(p. 80\)](#).

```
// Instantiate the AWS Encryption SDK and material providers  
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();  
var materialProviders =  
  
    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();  
  
string additionalKey = "arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-  
ab0987654321";  
  
// Instantiate a KMS keyring for one AWS KMS key.  
var kmsDecryptKeyringInput = new CreateAwsKmsKeyringInput  
{  
    KmsClient = new AmazonKeyManagementServiceClient(),  
    KmsKeyId = additionalKey  
};  
  
var kmsDecryptKeyring = materialProviders.CreateAwsKmsKeyring(kmsDecryptKeyringInput);
```

JavaScript Browser

```
const clientProvider = getClient(KMS, { credentials })
```

```
const additionalKey = 'arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321'

const keyring = new KmsKeyringBrowser({ clientProvider, keyIds: [additionalKey] })
```

JavaScript Node.js

```
const additionalKey = 'arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321'

const keyring = new KmsKeyringNode({ keyIds: [additionalKey] })
```

You can also use an AWS KMS keyring that specifies a generator key for decrypting, such as the following one. When decrypting, the AWS Encryption SDK ignores the distinction between generator keys and additional keys. It can use any of the specified AWS KMS keys to decrypt an encrypted data key. The call to AWS KMS succeeds only when the caller has permission to use that AWS KMS key to decrypt data.

C

```
struct aws_cryptosdk_keyring *kms_decrypt_keyring =
    Aws::Cryptosdk::KmsKeyring::Builder().Build(generator_key, {additional_key,
    other_key});
```

C# / .NET

```
// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

string generatorKey = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

// Instantiate a KMS keyring for one AWS KMS key.
var kmsDecryptKeyringInput = new CreateAwsKmsKeyringInput
{
    KmsClient = new AmazonKeyManagementServiceClient(),
    KmsKeyId = generatorKey
};

var kmsDecryptKeyring = materialProviders.CreateAwsKmsKeyring(kmsDecryptKeyringInput);
```

JavaScript Browser

```
const clientProvider = getClient(KMS, { credentials })

const keyring = new KmsKeyringBrowser({
    clientProvider,
    generatorKeyId,
    keyIds: [additionalKey, otherKey]
})
```

JavaScript Node.js

```
const keyring = new KmsKeyringNode({
    generatorKeyId,
    keyIds: [additionalKey, otherKey]
})
```

Unlike an encryption keyring that uses all of the specified AWS KMS keys, you can decrypt an encrypted message using a decryption keyring that includes AWS KMS keys that are unrelated to the encrypted message, and AWS KMS keys that the caller doesn't have permission to use. If a decrypt call to AWS KMS fails, such as when the caller doesn't have the required permission, the AWS Encryption SDK just skips to the next encrypted data key.

Using an AWS KMS discovery keyring

When decrypting, it's a [best practice \(p. 17\)](#) to specify the wrapping keys that the AWS Encryption SDK can use. To follow this best practice, use an AWS KMS decryption keyring that limits the AWS KMS wrapping keys to those that you specify. However, you can also create an *AWS KMS discovery keyring*, that is, an AWS KMS keyring that doesn't specify any wrapping keys.

The AWS Encryption SDK provides a standard AWS KMS discovery keyring and a discovery keyring for AWS KMS multi-Region keys. For information about using multi-Region keys with the AWS Encryption SDK, see [Use multi-Region AWS KMS keys \(p. 21\)](#).

Because it doesn't specify any wrapping keys, a discovery keyring can't encrypt data. If you use a discovery keyring to encrypt data, alone or in a multi-keyring, the encrypt operation fails. The exception is the AWS Encryption SDK for C, where the encrypt operation ignores a standard discovery keyring, but fails if you specify a multi-Region discovery keyring, alone or in a multi-keyring.

When decrypting, a discovery keyring allows the AWS Encryption SDK to ask AWS KMS to decrypt any encrypted data key by using the AWS KMS key that encrypted it, regardless of who owns or has access to that AWS KMS key. The call succeeds only when the caller has `kms:Decrypt` permission on the AWS KMS key.

Important

If you include an AWS KMS discovery keyring in a decryption [multi-keyring \(p. 64\)](#), the discovery keyring overrides all KMS key restrictions specified by other keyrings in the multi-keyring. The multi-keyring behaves like its least restrictive keyring. An AWS KMS discovery keyring has no effect on encryption when used by itself or in a multi-keyring.

If you use a discovery keyring, we recommend that you use a *discovery filter* to limit the KMS keys that can be used to those in specified AWS accounts and partitions. Discovery filters are supported in versions 1.7.x and later of the AWS Encryption SDK. For help finding your account ID and partition, see [Your AWS account identifiers](#) and [ARN format](#) in the *AWS General Reference*.

The AWS Encryption SDK provides an AWS KMS discovery keyring for convenience. However, we recommend that you use a more limited keyring whenever possible for the following reasons.

- **Authenticity** – An AWS KMS discovery keyring can use any AWS KMS key that was used to encrypt a data key in the encrypted message, just so the caller has permission to use that AWS KMS key to decrypt. This might not be the AWS KMS key that the caller intends to use. For example, one of the encrypted data keys might have been encrypted under a less secure AWS KMS key that anyone can use.
- **Latency and performance** – An AWS KMS discovery keyring might be perceptibly slower than other keyrings because the AWS Encryption SDK tries to decrypt all of the encrypted data keys, including those encrypted by AWS KMS keys in other AWS accounts and Regions, and AWS KMS keys that the caller doesn't have permission to use for decryption.

The following code instantiates an AWS KMS discovery keyring with a discovery filter that limits the KMS keys the AWS Encryption SDK can use to those in the 111122223333 example account.

C

For a complete example, see: [kms_discovery.cpp](#).

```
std::shared_ptr<KmsKeyring> discovery_filter(
```

```
KmsKeyring::DiscoveryFilter::Builder("aws")
    .AddAccount("111122223333")
    .Build();

struct aws_cryptosdk_keyring *kms_discovery_keyring =
    Aws::Cryptosdk::KmsKeyring::Builder()
        .BuildDiscovery(discovery_filter));
```

C# / .NET

```
// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

List<string> account = new List<string> { "111122223333" };

// In a discovery keyring, you specify an AWS KMS client and a discovery filter,
// but not a AWS KMS key
var kmsDiscoveryKeyringInput = new CreateAwsKmsDiscoveryKeyringInput
{
    KmsClient = new AmazonKeyManagementServiceClient(),
    DiscoveryFilter = new DiscoveryFilter()
    {
        AccountIds = account,
        Partition = "aws"
    }
};

var kmsDiscoveryKeyring =
    materialProviders.CreateAwsKmsDiscoveryKeyring(kmsDiscoveryKeyringInput);
```

JavaScript Browser

In JavaScript, you must explicitly specify the discovery property.

```
const clientProvider = getClient(KMS, { credentials })

const discovery = true
const keyring = new KmsKeyringBrowser(clientProvider, {
    discovery,
    discoveryFilter: { accountIDs: [111122223333], partition: 'aws' }
})
```

JavaScript Node.js

In JavaScript, you must explicitly specify the discovery property.

```
const discovery = true

const keyring = new KmsKeyringNode({
    discovery,
    discoveryFilter: { accountIDs: ['111122223333'], partition: 'aws' }
})
```

Using an AWS KMS regional discovery keyring

An *AWS KMS regional discovery keyring* is a keyring that doesn't specify the ARNs of KMS keys. Instead, it allows the AWS Encryption SDK to decrypt using only the KMS keys in particular AWS Regions.

When decrypting with an AWS KMS regional discovery keyring, the AWS Encryption SDK decrypts any encrypted data key that was encrypted under an AWS KMS key in the specified AWS Region. To succeed, the caller must have `kms:Decrypt` permission on at least one of the AWS KMS keys in the specified AWS Region that encrypted a data key.

Like other discovery keyrings, the regional discovery keyring has no effect on encryption. It works only when decrypting encrypted messages. If you use a regional discovery keyring in a multi-keyring that is used for encrypting and decrypting, it is effective only when decrypting. If you use a multi-Region discovery keyring to encrypt data, alone or in a multi-keyring, the encrypt operation fails.

Important

If you include an AWS KMS regional discovery keyring in a decryption [multi-keyring \(p. 64\)](#), the regional discovery keyring overrides all KMS key restrictions specified by other keyrings in the multi-keyring. The multi-keyring behaves like its least restrictive keyring. An AWS KMS discovery keyring has no effect on encryption when used by itself or in a multi-keyring.

The regional discovery keyring in the AWS Encryption SDK for C attempts to decrypt only with KMS keys in the specified Region. When you use a discovery keyring in the AWS Encryption SDK for JavaScript and AWS Encryption SDK for .NET, you configure the Region on the AWS KMS client. These AWS Encryption SDK implementations don't filter KMS keys by Region, but AWS KMS will fail a decrypt request for KMS keys outside of the specified Region.

If you use a discovery keyring, we recommend that you use a *discovery filter* to limit the KMS keys used in decryption to those in specified AWS accounts and partitions. Discovery filters are supported in versions 1.7.x and later of the AWS Encryption SDK.

For example, the following code creates an AWS KMS regional discovery keyring with a discovery filter. This keyring limits the AWS Encryption SDK to KMS keys in account 111122223333 in the US West (Oregon) Region (us-west-2).

C

To view this keyring, and the `create_kms_client` method, in a working example, see [kms_discovery.cpp](#).

```
std::shared_ptr<KmsKeyring::DiscoveryFilter> discovery_filter(  
    KmsKeyring::DiscoveryFilter::Builder("aws")  
        .AddAccount("111122223333")  
        .Build());  
  
struct aws_cryptosdk_keyring *kms_regional_keyring =  
    Aws::Cryptosdk::KmsKeyring::Builder()  
        .WithKmsClient(create_kms_client(Aws::Region::US_WEST_2)).BuildDiscovery(discovery_filter));
```

C# / .NET

The AWS Encryption SDK for .NET does not have a dedicated regional discovery keyring. However, you can use several techniques to limit the KMS keys used when decrypting to a particular Region.

The most efficient way to limit the Regions in a discovery keyring is to use a multi-Region-aware discovery keyring, even if you encrypted the data using only single-Region keys. When it encounters single-Region keys, the multi-Region-aware keyring does not use any multi-Region features.

The keyring returned by the `CreateAwsKmsMrkDiscoveryKeyring()` method filters KMS keys by Region before calling AWS KMS. It sends a decrypt request to AWS KMS only when the encrypted data key was encrypted by a KMS key in the Region specified by the `Region` parameter in the `CreateAwsKmsMrkDiscoveryKeyringInput` object.

```
// Instantiate the AWS Encryption SDK and material providers
```

```
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

List<string> account = new List<string> { "111122223333" };

// Create the discovery filter
var filter = DiscoveryFilter = new DiscoveryFilter
{
    AccountIds = account,
    Partition = "aws"
};

var regionalDiscoveryKeyringInput = new CreateAwsKmsMrkDiscoveryKeyringInput
{
    KmsClient = new AmazonKeyManagementServiceClient(RegionEndpoint.USWest2),
    Region = RegionEndpoint.USWest2,
    DiscoveryFilter = filter
};

var kmsRegionalDiscoveryKeyring =
    materialProviders.CreateAwsKmsMrkDiscoveryKeyring(regionalDiscoveryKeyringInput);
```

You can also limit KMS keys to a particular AWS Region by specifying a Region in your instance of the AWS KMS client ([AmazonKeyManagementServiceClient](#)). However, this configuration is less efficient and potentially more costly than using a multi-Region-aware discovery keyring. Instead of filtering KMS keys by Region before calling AWS KMS, the AWS Encryption SDK for .NET calls AWS KMS for each encrypted data key (until it decrypts one) and relies on AWS KMS to limit the KMS keys it uses to the specified Region.

```
// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

List<string> account = new List<string> { "111122223333" };

// Create the discovery filter,
// but not a AWS KMS key
var createRegionalDiscoveryKeyringInput = new CreateAwsKmsDiscoveryKeyringInput
{
    KmsClient = new AmazonKeyManagementServiceClient(RegionEndpoint.USWest2),
    DiscoveryFilter = new DiscoveryFilter()
    {
        AccountIds = account,
        Partition = "aws"
    }
};

var kmsRegionalDiscoveryKeyring =
    materialProviders.CreateAwsKmsDiscoveryKeyring(createRegionalDiscoveryKeyringInput);
```

JavaScript Browser

```
const clientProvider = getClient(KMS, { credentials })

const discovery = true
const clientProvider = limitRegions(['us-west-2'], getKmsClient)
const keyring = new KmsKeyringBrowser(clientProvider, {
    discovery,
    discoveryFilter: { accountIDs: ['111122223333'], partition: 'aws' }
```

```
}}
```

JavaScript Node.js

To view this keyring, and the `limitRegions` and `function`, in a working example, see [kms_regional_discovery.ts](#).

```
const discovery = true
const clientProvider = limitRegions(['us-west-2'], getKmsClient)
const keyring = new KmsKeyringNode({
  clientProvider,
  discovery,
  discoveryFilter: { accountIDs: ['111122223333'], partition: 'aws' }
})
```

The AWS Encryption SDK for JavaScript also exports an `excludeRegions` function for Node.js and the browser. This function creates an AWS KMS regional discovery keyring that omits AWS KMS keys in particular regions. The following example creates an AWS KMS regional discovery keyring that can use AWS KMS keys in account 111122223333 in every AWS Region except for US East (N. Virginia) (us-east-1).

The AWS Encryption SDK for C does not have an analogous method, but you can implement one by creating a custom [ClientSupplier](#).

This example shows the code for Node.js.

```
const discovery = true
const clientProvider = excludeRegions(['us-east-1'], getKmsClient)
const keyring = new KmsKeyringNode({
  clientProvider,
  discovery,
  discoveryFilter: { accountIDs: ['111122223333'], partition: 'aws' }
})
```

Raw AES keyrings

The AWS Encryption SDK lets you use an AES symmetric key that you provide as a wrapping key that protects your data key. You need to generate, store, and protect the key material, preferably in a hardware security module (HSM) or key management system. Use a Raw AES keyring when you need to provide the wrapping key and encrypt the data keys locally or offline.

The Raw AES keyring encrypts data by using the AES-GCM algorithm and a wrapping key that you specify as a byte array. You can specify only one wrapping key in each Raw AES keyring, but you can include multiple Raw AES keyrings, alone or with other keyrings, in a [multi-keyring \(p. 64\)](#).

The Raw AES keyring is equivalent to and interoperates with the [JceMasterKey](#) class in the AWS Encryption SDK for Java and the [RawMasterKey](#) class in the AWS Encryption SDK for Python when they are used with an AES encryption keys. You can encrypt data with one implementation and decrypt the data with any other implementation using the same wrapping key. For details, see [Keyring compatibility \(p. 47\)](#).

Key namespaces and names

To identify the AES key in a keyring, the Raw AES keyring uses a *key namespace* and *key name* that you provide. These values are not secret. They appear in plain text in the header of the [encrypted message \(p. 8\)](#) that the encrypt operation returns. We recommend using a key namespace your HSM or key management system and a key name that identifies the AES key in that system.

Note

The key namespace and key name are equivalent to the *Provider ID* (or *Provider*) and *Key ID* fields in the `JceMasterKey` and `RawMasterKey`.

The AWS Encryption SDK for C and AWS Encryption SDK for .NET reserve the `aws-kms` key namespace value for KMS keys. Do not use this namespace value in a Raw AES keyring or Raw RSA keyring with these libraries.

If you construct different keyrings to encrypt and decrypt a given message, the namespace and name values are critical. If the key namespace and key name in the decryption keyring isn't an exact, case-sensitive match for the key namespace and key name in the encryption keyring, the decryption keyring isn't used, even if the key material bytes are identical.

For example, you might define a Raw AES keyring with key namespace `HSM_01` and key name `AES_256_012`. Then, you use that keyring to encrypt some data. To decrypt that data, construct a Raw AES keyring with the same key namespace, key name, and key material.

The following examples show how to create a Raw AES keyring. The `AESWrappingKey` variable represents the key material you provide.

C

To instantiate a Raw AES keyring in the AWS Encryption SDK for C, use `aws_cryptosdk_raw_aes_keyring_new()`. For a complete example, see [raw_aes_keyring.c](#).

```
struct aws_allocator *alloc = aws_default_allocator();

AWS_STATIC_STRING_FROM_LITERAL(wrapping_key_namespace, "HSM_01");
AWS_STATIC_STRING_FROM_LITERAL(wrapping_key_name, "AES_256_012");

struct aws_cryptosdk_keyring *raw_aes_keyring = aws_cryptosdk_raw_aes_keyring_new(
    alloc, wrapping_key_namespace, wrapping_key_name, aes_wrapping_key,
    wrapping_key_len);
```

C# / .NET

To create a Raw AES keyring in AWS Encryption SDK for .NET, use the `materialProviders.CreateRawAesKeyring()` method. For a complete example, see [RawAesKeyringExample.cs](#)

```
// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

var keyNamespace = "HSM_01";
var keyName = "AES_256_012";

// This example uses the key generator in Bouncy Castle to generate the key material.
// In production, use key material from a secure source.
var aesWrappingKey = new
    MemoryStream(GeneratorUtilities.GetKeyGenerator("AES256").GenerateKey());

// Create the keyring that determines how your data keys are protected.
var createKeyringInput = new CreateRawAesKeyringInput
{
    KeyNamespace = keyNamespace,
    KeyName = keyName,
    WrappingKey = aesWrappingKey,
    WrappingAlg = AesWrappingAlg.ALG_AES256_GCM_IV12_TAG16
};
```

```
var keyring = materialProviders.CreateRawAesKeyring(createKeyringInput);
```

JavaScript Browser

The AWS Encryption SDK for JavaScript in the browser gets its cryptographic primitives from the [WebCrypto](#) API. Before you construct the keyring, you must use `RawAesKeyringWebCrypto.importCryptoKey()` to import the raw key material into the WebCrypto backend. This assures that the keyring is complete even though all calls to WebCrypto are asynchronous.

Then, to instantiate a Raw AES keyring, use the `RawAesKeyringWebCrypto()` method. You must specify the AES wrapping algorithm ("wrapping suite") based on the length of your key material. For a complete example, see [aes_simple.ts \(JavaScript Browser\)](#).

```
const keyNamespace = 'HSM_01'
const keyName = 'AES_256_012'

const wrappingSuite =
  RawAesWrappingSuiteIdentifier.AES256_GCM_IV12_TAG16_NO_PADDING

/* Import the plaintext AES key into the WebCrypto backend. */
const aesWrappingKey = await RawAesKeyringWebCrypto.importCryptoKey(
  rawAesKey,
  wrappingSuite
)

const rawAesKeyring = new RawAesKeyringWebCrypto({
  keyName,
  keyNamespace,
  wrappingSuite,
  aesWrappingKey
})
```

JavaScript Node.js

To instantiate a Raw AES keyring in the AWS Encryption SDK for JavaScript for Node.js, create an instance of the `RawAesKeyringNode` class. You must specify the AES wrapping algorithm ("wrapping suite") based on the length of your key material. For a complete example, see [aes_simple.ts \(JavaScript Node.js\)](#).

```
const keyName = 'AES_256_012'
const keyNamespace = 'HSM_01'

const wrappingSuite =
  RawAesWrappingSuiteIdentifier.AES256_GCM_IV12_TAG16_NO_PADDING

const rawAesKeyring = new RawAesKeyringNode({
  keyName,
  keyNamespace,
  aesWrappingKey,
  wrappingSuite,
})
```

Raw RSA keyrings

The Raw RSA keyring performs asymmetric encryption and decryption of data keys in local memory with an RSA public and private keys that you provide. You need to generate, store, and protect the private key, preferably in a hardware security module (HSM) or key management system. The encryption function

encrypts the data key under the RSA public key. The decryption function decrypts the data key using the private key. You can select from among the several [RSA padding modes](#).

A Raw RSA keyring that encrypts and decrypts must include an asymmetric public key and private key pair. However, you can encrypt data with a Raw RSA keyring that has only a public key, and you can decrypt data with a Raw RSA keyring that has only a private key. You can include any Raw RSA keyring in a [multi-keyring](#) (p. 64). If you configure a Raw RSA keyring with a public and private key, be sure that they are part of the same key pair. Some language implementations of the AWS Encryption SDK will not construct a Raw RSA keyring with keys from different pairs. Others rely on you to verify that your keys are from the same key pair.

The Raw RSA keyring is equivalent to and interoperates with the [JceMasterKey](#) in the AWS Encryption SDK for Java and the [RawMasterKey](#) in the AWS Encryption SDK for Python when they are used with RSA asymmetric encryption keys. You can encrypt data with one implementation and decrypt the data with any other implementation using the same wrapping key. For details, see [Keyring compatibility](#) (p. 47).

Note

Do not use an [asymmetric KMS key](#) in a Raw RSA keyring. The Raw RSA keyring does not support KMS keys.

If you encrypt data with a Raw RSA keyring that includes the public key of an RSA KMS key, neither the AWS Encryption SDK nor AWS KMS can decrypt it. You cannot export the private key of an AWS KMS asymmetric KMS key into a Raw RSA keyring. The AWS KMS Decrypt operation cannot decrypt the [encrypted message](#) (p. 8) that the AWS Encryption SDK returns.

When constructing a Raw RSA keyring in the AWS Encryption SDK for C, be sure to provide the *contents* of the PEM file that includes each key as a null-terminated C-string, not as a path or file name. When constructing a Raw RSA keyring in JavaScript, be aware of [potential incompatibility](#) (p. 95) with other language implementations.

Namespaces and names

To identify the RSA key material in a keyring, the Raw RSA keyring uses a *key namespace* and *key name* that you provide. These values are not secret. They appear in plain text in the header of the [encrypted message](#) (p. 8) that the encrypt operation returns. We recommend using the key namespace and key name that identifies the RSA key pair (or its private key) in your HSM or key management system.

Note

The key namespace and key name are equivalent to the *Provider ID* (or *Provider*) and *Key ID* fields in the [JceMasterKey](#) and [RawMasterKey](#).

The AWS Encryption SDK for C reserves the `aws-kms` key namespace value for KMS keys. Do not use it in a Raw AES keyring or Raw RSA keyring with the AWS Encryption SDK for C.

If you construct different keyrings to encrypt and decrypt a given message, the namespace and name values are critical. If the key namespace and key name in the decryption keyring isn't an exact, case-sensitive match for the key namespace and key name in the encryption keyring, the decryption keyring isn't used, even if the keys are from the same key pair.

The key namespace and key name of the key material in the encryption and decryption keyrings must be same whether the keyring contains the RSA public key, the RSA private key, or both keys in the key pair. For example, suppose you encrypt data with a Raw RSA keyring for an RSA public key with key namespace `HSM_01` and key name `RSA_2048_06`. To decrypt that data, construct a Raw RSA keyring with the private key (or key pair), and the same key namespace and name.

Padding mode

You must specify a padding mode for Raw RSA keyrings used for encryption and decryption, or use features of your language implementation that specify it for you.

The AWS Encryption SDK supports the following padding modes, subjects to the constraints of each language. We recommend an [OAEP](#) padding mode, particularly OAEP with SHA-256 and MGF1 with SHA-256 Padding. The [PKCS1](#) padding mode is supported only for backward compatibility.

- OAEP with SHA-1 and MGF1 with SHA-1 Padding
- OAEP with SHA-256 and MGF1 with SHA-256 Padding
- OAEP with SHA-384 and MGF1 with SHA-384 Padding
- OAEP with SHA-512 and MGF1 with SHA-512 Padding
- PKCS1 v1.5 Padding

The following examples show how to create a Raw RSA keyring with the public and private key of an RSA key pair and the OAEP with SHA-256 and MGF1 with SHA-256 padding mode. The `RSAPublicKey` and `RSAPrivateKey` variables represent the key material you provide.

C

To create a Raw RSA keyring in the AWS Encryption SDK for C, use `aws_cryptosdk_raw_rsa_keyring_new`.

When constructing a Raw RSA keyring in the AWS Encryption SDK for C, be sure to provide the *contents* of the PEM file that includes each key as a null-terminated C-string, not as a path or file name. For a complete example, see [raw_rsa_keyring.c](#).

```
struct aws_allocator *alloc = aws_default_allocator();

AWS_STATIC_STRING_FROM_LITERAL(key_namespace, "HSM_01");
AWS_STATIC_STRING_FROM_LITERAL(key_name, "RSA_2048_06");

struct aws_cryptosdk_keyring *rawRsaKeyring = aws_cryptosdk_raw_rsa_keyring_new(
    alloc,
    key_namespace,
    key_name,
    private_key_from_pem,
    public_key_from_pem,
    AWS_CRYPTOSDK_RSA_OAEP_SHA256_MGF1);
```

C# / .NET

To instantiate a Raw RSA keyring in the AWS Encryption SDK for .NET, use the `materialProviders.CreateRawRsaKeyring()` method. For a complete example, see [RawRSAKeyringExample.cs](#).

```
// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

var keyNamespace = "HSM_01";
var keyName = "RSA_2048_06";

// Get public and private keys from PEM files
var publicKey = new
    MemoryStream(System.IO.File.ReadAllBytes("RSAKeyringExamplePublicKey.pem"));
var privateKey = new
    MemoryStream(System.IO.File.ReadAllBytes("RSAKeyringExamplePrivateKey.pem"));

// Create the keyring input
var createRawRsaKeyringInput = new CreateRawRsaKeyringInput
{
    KeyNamespace = keyNamespace,
    KeyName = keyName,
    PaddingScheme = PaddingScheme.OAEP_SHA512_MGF1,
    PublicKey = publicKey,
```

```
    PrivateKey = privateKey
  };

  // Create the keyring
  var rawRsaKeyring = materialProviders.CreateRawRsaKeyring(createRawRsaKeyringInput);
```

JavaScript Browser

The AWS Encryption SDK for JavaScript in the browser gets its cryptographic primitives from the [WebCrypto](#) library. Before you construct the keyring, you must use `importPublicKey()` and/or `importPrivateKey()` to import the raw key material into the WebCrypto backend. This assures that the keyring is complete even though all calls to WebCrypto are asynchronous. The object that the import methods take includes the wrapping algorithm and its padding mode.

After importing the key material, use the `RawRsaKeyringWebCrypto()` method to instantiate the keyring. When constructing a Raw RSA keyring in JavaScript, be aware of [potential incompatibility \(p. 95\)](#) with other language implementations.

For a complete example, see [rsa_simple.ts](#) (JavaScript Browser).

```
const privateKey = await RawRsaKeyringWebCrypto.importPrivateKey(
  privateKeyJwkKey
)

const publicKey = await RawRsaKeyringWebCrypto.importPublicKey(
  publicKeyJwkKey
)

const keyNamespace = 'HSM_01'
const keyName = 'RSA_2048_06'

const keyring = new RawRsaKeyringWebCrypto({
  keyName,
  keyNamespace,
  publicKey,
  privateKey,
})
```

JavaScript Node.js

To instantiate a Raw RSA keyring in AWS Encryption SDK for JavaScript for Node.js, create a new instance of the `RawRsaKeyringNode` class. The `wrapKey` parameter holds the public key. The `unwrapKey` parameter holds the private key. The `RawRsaKeyringNode` constructor calculates a default padding mode for you, although you can specify a preferred padding mode.

When constructing a raw RSA keyring in JavaScript, be aware of [potential incompatibility \(p. 95\)](#) with other language implementations.

For a complete example, see [rsa_simple.ts](#) (JavaScript Node.js).

```
const keyNamespace = 'HSM_01'
const keyName = 'RSA_2048_06'

const keyring = new RawRsaKeyringNode({ keyName, keyNamespace, rsaPublicKey,
  rsaPrivateKey})
```

Multi-keyrings

You can combine keyrings into a multi-keyring. A *multi-keyring* is a keyring that consists of one or more individual keyrings of the same or a different type. The effect is like using several keyrings in a series.

When you use a multi-keyring to encrypt data, any of the wrapping keys in any of its keyrings can decrypt that data.

When you create a multi-keyring to encrypt data, you designate one of the keyrings as the *generator keyring*. All other keyrings are known as *child keyrings*. The generator keyring generates and encrypts the plaintext data key. Then, all of the wrapping keys in all of the child keyrings encrypt the same plaintext data key. The multi-keyring returns the plaintext key and one encrypted data key for each wrapping key in the multi-keyring. If you create a multi-keyring with no generator keyring, you can use it to decrypt data, but not to encrypt. If the generator keyring is a [KMS keyring \(p. 49\)](#), the generator key in the AWS KMS keyring generates and encrypts the plaintext key. Then, all additional AWS KMS keys in the AWS KMS keyring, and all wrapping keys in all child keyrings in the multi-keyring, encrypt the same plaintext key.

When decrypting, the AWS Encryption SDK uses the keyrings to try to decrypt one of the encrypted data keys. The keyrings are called in the order that they are specified in the multi-keyring. Processing stops as soon as any key in any keyring can decrypt an encrypted data key.

Beginning in [version 1.7.x \(p. 195\)](#), when an encrypted data key is encrypted under an AWS Key Management Service (AWS KMS) keyring (or master key provider), the AWS Encryption SDK always passes the key ARN of the AWS KMS key to the `KeyId` parameter of the AWS KMS [Decrypt](#) operation. This is an AWS KMS best practice that assures that you decrypt the encrypted data key with the wrapping key you intend to use.

To see a working example of a multi-keyring, see:

- C: [multi_keyring.cpp](#)
- C# / .NET: [MultiKeyringExample.cs](#)
- JavaScript Node.js: [multi_keyring.ts](#)
- JavaScript Browser: [multi_keyring.ts](#)

To create a multi-keyring, first instantiate the child keyrings. In this example, we use an AWS KMS keyring and a Raw AES keyring, but you can combine any supported keyrings in a multi-keyring.

C

```
/* Define an AWS KMS keyring. For details, see string.cpp */
struct aws_cryptosdk_keyring *kms_keyring =
    Aws::Cryptosdk::KmsKeyring::Builder().Build(example_key);

// Define a Raw AES keyring. For details, see raw\_aes\_keyring.c */
struct aws_cryptosdk_keyring *aes_keyring = aws_cryptosdk_raw_aes_keyring_new(
    alloc, wrapping_key_namespace, wrapping_key_name, wrapping_key,
    AWS_CRYPTOSDK_AES256);
```

C# / .NET

```
// Define an AWS KMS keyring. For details, see AwsKmsKeyringExample.cs.
var kmsKeyring = materialProviders.CreateAwsKmsKeyring(createKmsKeyringInput);

// Define a Raw AES keyring. For details, see RawAESKeyringExample.cs.
var aesKeyring = materialProviders.CreateRawAesKeyring(createAesKeyringInput);
```

JavaScript Browser

```
const clientProvider = getClient(KMS, { credentials })
```

```
// Define an AWS KMS keyring. For details, see kms_simple.ts.
const kmsKeyring = new KmsKeyringBrowser({ generatorKeyId: exampleKey })

// Define a Raw AES keyring. For details, see aes_simple.ts.
const aesKeyring = new RawAesKeyringWebCrypto({ keyName, keyNamespace, wrappingSuite,
masterKey })
```

JavaScript Node.js

```
// Define an AWS KMS keyring. For details, see kms_simple.ts.
const kmsKeyring = new KmsKeyringNode({ generatorKeyId: exampleKey })

// Define a Raw AES keyring. For details, see raw_aes_keyring_node.ts.
const aesKeyring = new RawAesKeyringNode({ keyName, keyNamespace, wrappingSuite,
unencryptedMasterKey })
```

Next, create the multi-keyring and specify its generator keyring, if any. In this example, we create a multi-keyring in which the AWS KMS keyring is the generator keyring and the AES keyring is the child keyring.

C

In the multi-keyring constructor in C, you specify only its generator keyring.

```
struct aws_cryptosdk_keyring *multi_keyring = aws_cryptosdk_multi_keyring_new(alloc,
kms_keyring);
```

To add a child keyring to your multi-keyring, use the `aws_cryptosdk_multi_keyring_add_child` method. You need to call the method once for each child keyring that you add.

```
// Add the Raw AES keyring (C only)
aws_cryptosdk_multi_keyring_add_child(multi_keyring, aes_keyring);
```

C# / .NET

The `.NET CreateMultiKeyringInput` constructor lets you define a generator keyring and child keyrings. The resulting `CreateMultiKeyringInput` object is immutable.

```
var createMultiKeyringInput = new CreateMultiKeyringInput
{
    Generator = kmsKeyring,
    ChildKeyrings = new List<IKeyring>() {aesKeyring}
};

var multiKeyring = materialProviders.CreateMultiKeyring(createMultiKeyringInput);
```

JavaScript Browser

JavaScript multi-keyrings are immutable. The JavaScript multi-keyring constructor lets you specify the generator keyring and multiple child keyrings.

```
const clientProvider = getClient(KMS, { credentials })

const multiKeyring = new MultiKeyringWebCrypto(generator: kmsKeyring, children:
[aesKeyring]);
```

JavaScript Node.js

JavaScript multi-keyrings are immutable. The JavaScript multi-keyring constructor lets you specify the generator keyring and multiple child keyrings.

```
const multiKeyring = new MultiKeyringNode(generator: kmsKeyring, children:  
  [aesKeyring]);
```

Now, you can use the multi-keyring to encrypt and decrypt data.

For a complete example of how to build and use a multi-keyring in C, see [multi_keyring.cpp](#).

AWS Encryption SDK programming languages

The AWS Encryption SDK is available for the following programming languages. All language implementations are interoperable. You can encrypt with one language implementation and decrypt with another. Interoperability might be subject to language constraints. If so, these constraints are described in the topic about the language implementation. Also, when encrypting and decrypting, you must use compatible keyrings, or master keys and master key providers. For details, see [the section called “Keyring compatibility” \(p. 47\)](#).

Topics

- [AWS Encryption SDK for C \(p. 68\)](#)
- [AWS Encryption SDK for .NET \(p. 77\)](#)
- [AWS Encryption SDK for Java \(p. 85\)](#)
- [AWS Encryption SDK for JavaScript \(p. 95\)](#)
- [AWS Encryption SDK for Python \(p. 103\)](#)
- [AWS Encryption SDK command line interface \(p. 112\)](#)

AWS Encryption SDK for C

The AWS Encryption SDK for C provides a client-side encryption library for developers who are writing applications in C. It also serves as a foundation for implementations of the AWS Encryption SDK in higher-level programming languages.

Like all implementations of the AWS Encryption SDK, the AWS Encryption SDK for C offers advanced data protection features. These include [envelope encryption](#), additional authenticated data (AAD), and secure, authenticated, symmetric key [algorithm suites \(p. 9\)](#), such as 256-bit AES-GCM with key derivation and signing.

All language-specific implementations of the AWS Encryption SDK are fully interoperable. For example, you can encrypt data with the AWS Encryption SDK for C and decrypt it with [any supported language implementation \(p. 68\)](#), including the [AWS Encryption CLI \(p. 112\)](#).

The AWS Encryption SDK for C requires the AWS SDK for C++ to interact with AWS Key Management Service (AWS KMS). You need to use it only if you're using the optional [AWS KMS keyring \(p. 49\)](#). However, the AWS Encryption SDK doesn't require AWS KMS or any other AWS service.

Learn More

- For details about programming with the AWS Encryption SDK for C, see the [C examples \(p. 72\)](#), the [examples](#) in the [aws-encryption-sdk-c repository](#) on GitHub, and the [AWS Encryption SDK for C API documentation](#).
- For a discussion about how to use the AWS Encryption SDK for C to encrypt data so that you can decrypt it in multiple AWS Regions, see [How to decrypt ciphertexts in multiple regions with the AWS Encryption SDK in C](#) in the AWS Security Blog.

Topics

- [Installing the AWS Encryption SDK for C \(p. 69\)](#)
- [Using the AWS Encryption SDK for C \(p. 69\)](#)
- [AWS Encryption SDK for C examples \(p. 72\)](#)

Installing the AWS Encryption SDK for C

You can find detailed instructions for installing and building the AWS Encryption SDK for C in the [README file](#) of the `aws-encryption-sdk-c` repository. It includes instructions for building on Amazon Linux, Ubuntu, macOS, and Windows platforms.

Before you begin, decide whether you want to use [AWS KMS keyrings \(p. 49\)](#) in the AWS Encryption SDK. If you use an AWS KMS keyring, you need to install the AWS SDK for C++. The AWS SDK is required to interact with [AWS Key Management Service \(AWS KMS\)](#). When you use AWS KMS keyrings, the AWS Encryption SDK uses AWS KMS to generate and protect the encryption keys that protect your data.

You do not need to install the AWS SDK for C++ if you are using another keyring type, such as a raw AES keyring, a raw RSA keyring, or a multi-keyring that doesn't include an AWS KMS keyring. However, when using a raw keyring type, you need to generate and protect your own raw wrapping keys.

For help deciding which keyring types to use, see [the section called "Choosing a keyring" \(p. 48\)](#).

If you're having trouble with your installation, [file an issue](#) in the `aws-encryption-sdk-c` repository or use any of the feedback links on this page.

Using the AWS Encryption SDK for C

This topic explains some of the features of the AWS Encryption SDK for C that are not supported in other programming language implementations.

The examples in this section show how to use [version 2.0.x \(p. 194\)](#) and later of the AWS Encryption SDK for C. For examples that use earlier versions, find your release in the [Releases](#) list of the `aws-encryption-sdk-c` repository on GitHub.

For details about programming with the AWS Encryption SDK for C, see the [C examples \(p. 72\)](#), the [examples](#) in the `aws-encryption-sdk-c` repository on GitHub, and the [AWS Encryption SDK for C API documentation](#).

- [Reference counting \(p. 71\)](#)

Patterns for encrypting and decrypting data

When you use the AWS Encryption SDK for C, you follow a pattern similar to this: create a [keyring \(p. 7\)](#), create a [CMM \(p. 9\)](#) that uses the keyring, create a session that uses the CMM (and keyring), and then process the session.

1. Load error strings.

Call the `aws_cryptosdk_load_error_strings()` method in your C or C++ code. It loads error information that is very useful for debugging.

You only need to call it once, such as in your `main` method.

```
/* Load error strings for debugging */  
aws_cryptosdk_load_error_strings();
```

2. Create a keyring.

Configure your [keyring \(p. 7\)](#) with the wrapping keys that you want to use to encrypt your data keys. This example uses an [AWS KMS keyring \(p. 49\)](#) with one AWS KMS key, but you can use any type of keyring in its place.

To identify an AWS KMS key in an encryption keyring in the AWS Encryption SDK for C, specify a [key ARN](#) or [alias ARN](#). In a decryption keyring, you must use a key ARN. For details, see [Identifying AWS KMS keys in an AWS KMS keyring \(p. 50\)](#).

```
const char * KEY_ARN = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"  
struct aws_cryptosdk_keyring *kms_keyring =  
    Aws::Cryptosdk::KmsKeyring::Builder().Build(KEY_ARN);
```

3. Create a session.

In the AWS Encryption SDK for C, you use a *session* to encrypt a single plaintext message or decrypt a single ciphertext message, regardless of its size. The session maintains the state of the message throughout its processing.

Configure your session with an allocator, a keyring, and a mode: `AWS_CRYPTOSDK_ENCRYPT` or `AWS_CRYPTOSDK_DECRYPT`. If you need to change the mode of the session, use the `aws_cryptosdk_session_reset` method.

When you create a session with a keyring, the AWS Encryption SDK for C automatically creates a default cryptographic materials manager (CMM) for you. You don't need to create, maintain, or destroy this object.

For example, the following session uses the allocator and the keyring that was defined in step 1. When you encrypt data, the mode is `AWS_CRYPTOSDK_ENCRYPT`.

```
struct aws_cryptosdk_session * session =  
    aws_cryptosdk_session_new_from_keyring_2(allocator, AWS_CRYPTOSDK_ENCRYPT,  
        kms_keyring);
```

4. Encrypt or decrypt the data.

To process the data in the session, use the `aws_cryptosdk_session_process` method. If the input buffer is large enough to hold the entire plaintext, and the output buffer is large enough to hold the entire ciphertext, you can call `aws_cryptosdk_session_process_full`. However, if you need to handle streaming data, you can call `aws_cryptosdk_session_process` in a loop. For an example, see the [file_streaming.cpp](#) example. The `aws_cryptosdk_session_process_full` is introduced in AWS Encryption SDK versions 1.9.x and 2.2.x.

When the session is configured to encrypt data, the plaintext fields describe the input and the ciphertext fields describe the output. The plaintext field holds the message that you want to encrypt and the ciphertext field gets the [encrypted message \(p. 224\)](#) that the encrypt method returns.

```
/* Encrypting data */  
aws_cryptosdk_session_process_full(session,  
    ciphertext,  
    ciphertext_buffer_size,  
    &ciphertext_length,
```

```
plaintext,  
plaintext_length)
```

When the session is configured to decrypt data, the `ciphertext` fields describe the input and the `plaintext` fields describe the output. The `ciphertext` field holds the [encrypted message \(p. 224\)](#) that the `encrypt` method returned, and the `plaintext` field gets the plaintext message that the `decrypt` method returns.

To decrypt the data, call the `aws_cryptosdk_session_process_full` method.

```
/* Decrypting data */  
aws_cryptosdk_session_process_full(session,  
                                   plaintext,  
                                   plaintext_buffer_size,  
                                   &plaintext_length,  
                                   ciphertext,  
                                   ciphertext_length)
```

Reference counting

To prevent memory leaks, be sure to release your references to all objects that you create when you are finished with them. Otherwise, you end up with memory leaks. The SDK provides methods to make this task easier.

Whenever you create a parent object with one of the following child objects, the parent object gets and maintains a reference to the child object, as follows:

- A [keyring \(p. 7\)](#), such as creating a session with a keyring
- A default [cryptographic materials manager \(p. 9\)](#) (CMM), such as creating a session or custom CMM with a default CMM
- A [data key cache \(p. 152\)](#), such as creating a caching CMM with a keyring and cache

Unless you need an independent reference to the child object, you can release your reference to the child object as soon as you create the parent object. The remaining reference to the child object is released when the parent object is destroyed. This pattern ensures that you maintain the reference to each object only for as long as you need it, and you don't leak memory due to unreleased references.

You are only responsible for releasing references to the child objects that you create explicitly. You are not responsible for managing references to any objects that the SDK creates for you. If the SDK creates an object, such as the default CMM that the `aws_cryptosdk_caching_cmm_new_from_keyring` method adds to a session, the SDK manages the creation and destruction of the object and its references.

In the following example, when you create a session with a [keyring \(p. 7\)](#), the session gets a reference to the keyring, and maintains that reference until the session is destroyed. If you do not need to maintain an additional reference to the keyring, you can use the `aws_cryptosdk_keyring_release` method to release the keyring object as soon as the session is created. This method decrements the reference count for the keyring. The session's reference to the keyring is released when you call `aws_cryptosdk_session_destroy` to destroy the session.

```
// The session gets a reference to the keyring.  
struct aws_cryptosdk_session *session =  
    aws_cryptosdk_session_new_from_keyring_2(alloc, AWS_CRYPTOSDK_ENCRYPT, keyring);  
  
// After you create a session with a keyring, release the reference to the keyring object.
```

```
aws_cryptosdk_keyring_release(keyring);
```

For more complex tasks, such as reusing a keyring for multiple sessions or specifying an algorithm suite in a CMM, you might need to maintain an independent reference to the object. If so, don't call the release methods immediately. Instead, release your references when you are no longer using the objects, in addition to destroying the session.

This reference counting technique also works when you are using alternate CMMs, such as the caching CMM for [data key caching](#) (p. 152). When you create a caching CMM from a cache and a keyring, the caching CMM gets a reference to both objects. Unless you need them for another task, you can release your independent references to the cache and keyring as soon as the caching CMM is created. Then, when you create a session with the caching CMM, you can release your reference to the caching CMM.

Notice that you are only responsible for releasing references to objects that you create explicitly. Objects that the methods create for you, such as the default CMM that underlies the caching CMM, are managed by the method.

```
/ Create the caching CMM from a cache and a keyring.
struct aws_cryptosdk_cmm *caching_cmm =
    aws_cryptosdk_caching_cmm_new_from_keyring(allocator, cache, kms_keyring, NULL, 60,
        AWS_TIMESTAMP_SECS);

// Release your references to the cache and the keyring.
aws_cryptosdk_materials_cache_release(cache);
aws_cryptosdk_keyring_release(kms_keyring);

// Create a session with the caching CMM.
struct aws_cryptosdk_session *session = aws_cryptosdk_session_new_from_cmm_2(allocator,
    AWS_CRYPTOSDK_ENCRYPT, caching_cmm);

// Release your references to the caching CMM.
aws_cryptosdk_cmm_release(caching_cmm);

// ...

aws_cryptosdk_session_destroy(session);
```

AWS Encryption SDK for C examples

The following examples show you how to use the AWS Encryption SDK for C to encrypt and decrypt data.

The examples in this section show how to use versions 2.0.x and later of the AWS Encryption SDK for C. For examples that use earlier versions, find your release in the [Releases](#) list of the [aws-encryption-sdk-c repository](#) on GitHub.

When you install and build the AWS Encryption SDK for C, the source code for these and other examples are included in the `examples` subdirectory, and they are compiled and built into the `build` directory. You can also find them in the [examples](#) subdirectory of the [aws-encryption-sdk-c repository](#) on GitHub.

Topics

- [Encrypting and decrypting strings](#) (p. 72)

Encrypting and decrypting strings

The following example shows you how to use the AWS Encryption SDK for C to encrypt and decrypt a string.

This example features the [AWS KMS keyring \(p. 49\)](#), a type of keyring that uses an AWS KMS key in [AWS Key Management Service \(AWS KMS\)](#) to generate and encrypt data keys. The example includes code written in C++. The AWS Encryption SDK for C requires the AWS SDK for C++ to call AWS KMS when using AWS KMS keyrings. If you're using a keyring that doesn't interact with AWS KMS, such as a raw AES keyring, a raw RSA keyring, or a multi-keyring that doesn't include an AWS KMS keyring, the AWS SDK for C++ is not required.

For help creating an AWS KMS key, see [Creating Keys](#) in the *AWS Key Management Service Developer Guide*. For help identifying the AWS KMS keys in an AWS KMS keyring, see [Identifying AWS KMS keys in an AWS KMS keyring \(p. 50\)](#).

See the complete code sample: [string.cpp](#)

Topics

- [Encrypt a string \(p. 73\)](#)
- [Decrypt a string \(p. 75\)](#)

Encrypt a string

The first part of this example uses an AWS KMS keyring with one AWS KMS key to encrypt a plaintext string.

Step 1. Load error strings.

Call the `aws_cryptosdk_load_error_strings()` method in your C or C++ code. It loads error information that is very useful for debugging.

You only need to call it once, such as in your main method.

```
/* Load error strings for debugging */  
aws_cryptosdk_load_error_strings();
```

Step 2: Construct the keyring.

Create an AWS KMS keyring for encryption. The keyring in this example is configured with one AWS KMS key, but you can configure an AWS KMS keyring with multiple AWS KMS keys, including AWS KMS keys in different AWS Regions and different accounts.

To identify an AWS KMS key in an encryption keyring in the AWS Encryption SDK for C, specify a [key ARN](#) or [alias ARN](#). In a decryption keyring, you must use a key ARN. For details, see [Identifying AWS KMS keys in an AWS KMS keyring \(p. 50\)](#).

Identifying AWS KMS keys in an AWS KMS keyring (p. 50)

When you create a keyring with multiple AWS KMS keys, you specify the AWS KMS key used to generate and encrypt the plaintext data key, and an optional array of additional AWS KMS keys that encrypt the same plaintext data key. In this case, you specify only the generator AWS KMS key.

Before running this code, replace the example key ARN with a valid one.

```
const char * key_arn = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
struct aws_cryptosdk_keyring *kms_keyring =  
    Aws::Cryptosdk::KmsKeyring::Builder().Build(key_arn);
```

Step 3: Create a session.

Create a session using the allocator, a mode enumerator, and the keyring.

Every session requires a mode: either `AWS_CRYPTOSDK_ENCRYPT` to encrypt or `AWS_CRYPTOSDK_DECRYPT` to decrypt. To change the mode of an existing session, use the `aws_cryptosdk_session_reset` method.

After you create a session with the keyring, you can release your reference to the keyring using the method that the SDK provides. The session retains a reference to the keyring object during its lifetime. References to the keyring and session objects are released when you destroy the session. This [reference counting \(p. 71\)](#) technique helps to prevent memory leaks and to prevent the objects from being released while they are in use.

```
struct aws_cryptosdk_session *session =
    aws_cryptosdk_session_new_from_keyring_2(alloc, AWS_CRYPTOSDK_ENCRYPT,
    kms_keyring);

/* When you add the keyring to the session, release the keyring object */
aws_cryptosdk_keyring_release(kms_keyring);
```

Step 4: Set the encryption context.

An [encryption context \(p. 8\)](#) is arbitrary, non-secret additional authenticated data. When you provide an encryption context on encrypt, the AWS Encryption SDK cryptographically binds the encryption context to the ciphertext so that the same encryption context is required to decrypt the data. Using an encryption context is optional, but we recommend it as a best practice.

First, create a hash table that includes the encryption context strings.

```
/* Allocate a hash table for the encryption context */
int set_up_enc_ctx(struct aws_allocator *alloc, struct aws_hash_table *my_enc_ctx)

// Create encryption context strings
AWS_STATIC_STRING_FROM_LITERAL(enc_ctx_key1, "Example");
AWS_STATIC_STRING_FROM_LITERAL(enc_ctx_value1, "String");
AWS_STATIC_STRING_FROM_LITERAL(enc_ctx_key2, "Company");
AWS_STATIC_STRING_FROM_LITERAL(enc_ctx_value2, "MyCryptoCorp");

// Put the key-value pairs in the hash table
aws_hash_table_put(my_enc_ctx, enc_ctx_key1, (void *)enc_ctx_value1, &was_created)
aws_hash_table_put(my_enc_ctx, enc_ctx_key2, (void *)enc_ctx_value2, &was_created)
```

Get a mutable pointer to the encryption context in the session. Then, use the `aws_cryptosdk_enc_ctx_clone` function to copy the encryption context into the session. Keep the copy in `my_enc_ctx` so you can validate the value after decrypting the data.

The encryption context is part of the session, not a parameter passed to the session process function. This guarantees that the same encryption context is used for every segment of a message, even if the session process function is called multiple times to encrypt the entire message.

```
struct aws_hash_table *session_enc_ctx =
    aws_cryptosdk_session_get_enc_ctx_ptr_mut(session);

aws_cryptosdk_enc_ctx_clone(alloc, session_enc_ctx, my_enc_ctx)
```

Step 5: Encrypt the string.

To encrypt the plaintext string, use the `aws_cryptosdk_session_process_full` method with the session in encryption mode. This method, introduced in AWS Encryption SDK versions 1.9.x and

2.2.x, is designed for non-streaming encryption and decryption. To handle streaming data, call the `aws_cryptosdk_session_process` in a loop.

When encrypting, the plaintext fields are input fields; the ciphertext fields are output fields. When the processing is complete, the `ciphertext_output` field contains the [encrypted message \(p. 8\)](#), including the actual ciphertext, encrypted data keys, and the encryption context. You can decrypt this encrypted message by using the AWS Encryption SDK for any supported programming language.

```
/* Gets the length of the plaintext that the session processed */
size_t ciphertext_len_output;
if (AWS_OP_SUCCESS != aws_cryptosdk_session_process_full(session,
    ciphertext_output,
    ciphertext_buf_sz_output,
    &ciphertext_len_output,
    plaintext_input,
    plaintext_len_input)) {
    aws_cryptosdk_session_destroy(session);
    return 8;
}
```

Step 6: Clean up the session.

The final step destroys the session including references to the CMM and the keyring.

If you prefer, instead of destroying the session, you can reuse the session with the same keyring and CMM to decrypt the string, or to encrypt or decrypt other messages. To use the session for decrypting, use the `aws_cryptosdk_session_reset` method to change the mode to `AWS_CRYPTOSDK_DECRYPT`.

Decrypt a string

The second part of this example decrypts an encrypted message that contains the ciphertext of the original string.

Step 1: Load error strings.

Call the `aws_cryptosdk_load_error_strings()` method in your C or C++ code. It loads error information that is very useful for debugging.

You only need to call it once, such as in your main method.

```
/* Load error strings for debugging */
aws_cryptosdk_load_error_strings();
```

Step 2: Construct the keyring.

When you decrypt data in AWS KMS, you pass in the [encrypted message \(p. 8\)](#) that the encrypt API returned. The [Decrypt API](#) doesn't take an AWS KMS key as input. Instead, AWS KMS uses the same AWS KMS key to decrypt the ciphertext that it used to encrypt it. However, the AWS Encryption SDK lets you specify an AWS KMS keyring with AWS KMS keys on encrypt and decrypt.

On decrypt, you can configure a keyring with only the AWS KMS keys that you want to use to decrypt the encrypted message. For example, you might want to create a keyring with only the AWS KMS key that is used by a particular role in your organization. The AWS Encryption SDK will never use an AWS KMS key unless it appears in the decryption keyring. If the SDK can't decrypt the encrypted data keys by using the AWS KMS keys in the keyring that you provide, either because none of AWS KMS keys in the keyring were used to encrypt any of the data keys, or because the caller doesn't have permission to use the AWS KMS keys in the keyring to decrypt, the decrypt call fails.

When you specify an AWS KMS key for a decryption keyring, you must use its [key ARN](#). Alias ARNs are permitted only in encryption keyrings. For help identifying the AWS KMS keys in an AWS KMS keyring, see [Identifying AWS KMS keys in an AWS KMS keyring \(p. 50\)](#).

In this example, we specify a keyring configured with the same AWS KMS key used to encrypt the string. Before running this code, replace the example key ARN with a valid one.

```
const char * key_arn = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"  
  
struct aws_cryptosdk_keyring *kms_keyring =  
    Aws::Cryptosdk::KmsKeyring::Builder().Build(key_arn);
```

Step 3: Create a session.

Create a session using the allocator and the keyring. To configure the session for decryption, configure the session with the `AWS_CRYPTOSDK_DECRYPT` mode.

After you create a session with a keyring, you can release your reference to the keyring using the method that the SDK provides. The session retains a reference to the keyring object during its lifetime, and both the session and keyring are released when you destroy the session. This reference counting technique helps to prevent memory leaks and to prevent the objects from being released while they are in use.

```
struct aws_cryptosdk_session *session =  
    aws_cryptosdk_session_new_from_keyring_2(alloc, AWS_CRYPTOSDK_DECRYPT, kms_keyring);  
  
/* When you add the keyring to the session, release the keyring object */  
aws_cryptosdk_keyring_release(kms_keyring);
```

Step 4: Decrypt the string.

To decrypt the string, use the `aws_cryptosdk_session_process_full` method with the session that is configured for decryption. This method, introduced in AWS Encryption SDK versions 1.9.x and 2.2.x, is designed for non-streaming encryption and decryption. To handle streaming data, call the `aws_cryptosdk_session_process` in a loop.

When decrypting, the ciphertext fields are input fields and the plaintext fields are output fields. The `ciphertext_input` field holds the [encrypted message \(p. 224\)](#) that the encrypt method returned. When the processing is complete, the `plaintext_output` field contains the plaintext (decrypted) string.

```
size_t plaintext_len_output;  
  
if (AWS_OP_SUCCESS != aws_cryptosdk_session_process_full(session,  
    plaintext_output,  
    plaintext_buf_sz_output,  
    &plaintext_len_output,  
    ciphertext_input,  
    ciphertext_len_input)) {  
    aws_cryptosdk_session_destroy(session);  
    return 13;  
}
```

Step 5: Verify the encryption context.

Be sure that the actual encryption context — the one that was used to decrypt the message — contains the encryption context that you provided when encrypting the message. The actual encryption context might include extra pairs, because the [cryptographic materials manager \(p. 9\)](#) (CMM) can add pairs to the provided encryption context before encrypting the message.

In the AWS Encryption SDK for C, you are not required to provide an encryption context when decrypting because the encryption context is included in the encrypted message that the SDK returns. But, before it returns the plaintext message, your decrypt function should verify that all pairs in the provided encryption context appear in the encryption context that was used to decrypt the message.

First, get a read-only pointer to the hash table in the session. This hash table contains the encryption context that was used to decrypt the message.

```
const struct aws_hash_table *session_enc_ctx =  
    aws_cryptosdk_session_get_enc_ctx_ptr(session);
```

Then, loop through the encryption context in the `my_enc_ctx` hash table that you copied when encrypting. Verify that each pair in the `my_enc_ctx` hash table that was used to encrypt appears in the `session_enc_ctx` hash table that was used to decrypt. If any key is missing, or that key has a different value, stop processing and write an error message.

```
for (struct aws_hash_iter iter = aws_hash_iter_begin(my_enc_ctx); !  
    aws_hash_iter_done(&iter);  
    aws_hash_iter_next(&iter)) {  
    struct aws_hash_element *session_enc_ctx_kv_pair;  
    aws_hash_table_find(session_enc_ctx, iter.element.key, &session_enc_ctx_kv_pair)  
  
    if (!session_enc_ctx_kv_pair ||  
        !aws_string_eq(  
            (struct aws_string *)iter.element.value, (struct aws_string  
            *)session_enc_ctx_kv_pair->value)) {  
        fprintf(stderr, "Wrong encryption context!\n");  
        abort();  
    }  
}
```

Step 6: Clean up the session.

After you verify the encryption context, you can destroy the session, or reuse it. If you need to reconfigure the session, use the `aws_cryptosdk_session_reset` method.

```
aws_cryptosdk_session_destroy(session);
```

AWS Encryption SDK for .NET

The AWS Encryption SDK for .NET is a client-side encryption library for developers who are writing applications in C# and other .NET programming languages. It is supported on Windows, macOS, and Linux.

All [programming language \(p. 68\)](#) implementations of the AWS Encryption SDK are fully interoperable. For example, you can encrypt data with AWS Encryption SDK for .NET and decrypt it with any [supported programming language implementation \(p. 68\)](#), including the [AWS Encryption CLI \(p. 112\)](#), provided that you use [compatible keyrings and master key providers \(p. 47\)](#).

The AWS Encryption SDK for .NET differs from some of the other programming language implementations of the AWS Encryption SDK in the following ways:

- No support for [data key caching \(p. 152\)](#)
- No support for streaming data

- [No logging or stack traces \(p. 78\)](#) from the AWS Encryption SDK for .NET
- [Requires the AWS SDK for .NET \(p. 78\)](#)

The AWS Encryption SDK for .NET includes all of the security features introduced in versions 2.0.x and later of other language implementations of the AWS Encryption SDK. However, if you are using the AWS Encryption SDK for .NET to decrypt data that was encrypted by a pre-2.0.x version another language implementation of the AWS Encryption SDK, you might need to adjust your [commitment policy \(p. 11\)](#). For details, see [How to set your commitment policy \(p. 212\)](#).

The AWS Encryption SDK for .NET is a product of the AWS Encryption SDK in [Dafny](#), a formal verification language in which you write specifications, the code to implement them, and the proofs to test them. The result is a library that implements the features of the AWS Encryption SDK in a framework that assures functional correctness.

Learn More

- For examples showing how to configure options in the AWS Encryption SDK, such as specifying an alternate algorithm suite, limiting encrypted data keys, and using AWS KMS multi-Region keys, see [Configuring the AWS Encryption SDK \(p. 20\)](#).
- For details about programming with the AWS Encryption SDK for .NET, see the [aws-encryption-sdk-net](#) directory of the aws-encryption-sdk-dafny repository on GitHub.

Topics

- [Installing the AWS Encryption SDK for .NET \(p. 78\)](#)
- [Debugging the AWS Encryption SDK for .NET \(p. 78\)](#)
- [AWS KMS keyrings in the AWS Encryption SDK for .NET \(p. 79\)](#)
- [AWS Encryption SDK for .NET examples \(p. 80\)](#)

Installing the AWS Encryption SDK for .NET

The AWS Encryption SDK for .NET is available as the [AWS.EncryptionSDK](#) package in NuGet. For details about installing and building the AWS Encryption SDK for .NET, see the [README.md](#) file in the `aws-encryption-sdk-net` repository.

The AWS Encryption SDK for .NET supports .NET Framework 4.5.2 – 4.8 only on Windows. It supports .NET Core 3.0+ and .NET 5.0 and later on all supported operating systems.

The AWS Encryption SDK for .NET requires the AWS SDK for .NET even if you aren't using AWS Key Management Service (AWS KMS) keys. It's installed with the NuGet package. However, unless you are using AWS KMS keys, AWS Encryption SDK for .NET does not require an AWS account, AWS credentials, or interaction with any AWS service. For help setting up an AWS account if you need it, see [Using the AWS Encryption SDK with AWS KMS \(p. 16\)](#).

Debugging the AWS Encryption SDK for .NET

The AWS Encryption SDK for .NET does not generate any logs. Exceptions in the AWS Encryption SDK for .NET generate an exception message, but no stack traces.

To help you debug, be sure to enable logging in the AWS SDK for .NET. The logs and error messages from the AWS SDK for .NET can help you distinguish errors arising in the AWS SDK for .NET from those in the AWS Encryption SDK for .NET. For help with AWS SDK for .NET logging, see [AWSLogging](#) in the *AWS SDK for .NET Developer Guide*. (To see the topic, expand the **Open to view .NET Framework content** section.)

AWS KMS keyrings in the AWS Encryption SDK for .NET

The basic AWS KMS keyrings in the AWS Encryption SDK for .NET take only one KMS key. They also require an AWS KMS client, which gives you an opportunity to configure the client for the AWS Region of the KMS key.

To create a AWS KMS keyring with one or more wrapping keys, use a multi-keyring. The AWS Encryption SDK for .NET has a special multi-keyring that takes one or more AWS KMS keys, and a standard multi-keyring that takes one or more keyrings of any supported type. Some programmers prefer to use a multi-keyring method to create all of their keyrings, and the AWS Encryption SDK for .NET supports that strategy.

The AWS Encryption SDK for .NET provides basic single-key keyrings and multi-keyrings for all typical use-cases, including AWS KMS [multi-Region keys](#) (p. 21).

For example, to create a AWS KMS keyring with one AWS KMS key, you can use the `CreateAwsKmsKeyring()` method. This example creates a default AWS KMS client for the Region that contains the specified key.

```
// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

string keyArn = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

// Instantiate the keyring input object
var kmsKeyringInput = new CreateAwsKmsKeyringInput
{
    KmsClient = new AmazonKeyManagementServiceClient(),
    KmsKeyId = keyArn
};

// Create the keyring
var keyring = materialProviders.CreateAwsKmsKeyring(kmsKeyringInput);
```

To create a keyring with one or more AWS KMS keys, use the `CreateAwsKmsMultiKeyring()` method. This example uses two AWS KMS keys. To specify one KMS key, use only the `Generator` parameter. The `KmsKeyIds` parameter that specifies additional KMS keys is optional.

The input for this keyring doesn't take an AWS KMS client. Instead, the AWS Encryption SDK uses the default AWS KMS client for each Region represented by a KMS key in the keyring. For example, if the KMS key identified by the value of the `Generator` parameter is in the US West (Oregon) Region (us-west-2), the AWS Encryption SDK creates a default AWS KMS client for the us-west-2 Region. If you need to customize the AWS KMS client, use the `CreateAwsKmsKeyring()` method.

```
// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

string generatorKey = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
List<string> additionalKeys = new List<string> { "arn:aws:kms:us-
west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321" };

// Create the multi-keyring
var multiKeyring = materialProviders.CreateAwsKmsMultiKeyring(generatorKey, additionalKeys);
```

```
// Instantiate the keyring input object
var createEncryptKeyringInput = new CreateAwsKmsMultiKeyringInput
{
    Generator = generatorKey,
    KmsKeyIds = additionalKeys
};

var kmsEncryptKeyring =
    materialProviders.CreateAwsKmsMultiKeyring(createEncryptKeyringInput);
```

AWS Encryption SDK for .NET examples

The following examples show the basic coding patterns that you use when programming with the AWS Encryption SDK for .NET. Specifically, you instantiate the AWS Encryption SDK and the material providers library. Then, before calling each method, you instantiate an object that defines the input for the method. This is much like the coding pattern you use in the AWS SDK for .NET.

For examples showing how to configure options in the AWS Encryption SDK, such as specifying an alternate algorithm suite, limiting encrypted data keys, and using AWS KMS multi-Region keys, see [Configuring the AWS Encryption SDK \(p. 20\)](#).

For more examples of programming with the AWS Encryption SDK for .NET, see the [examples](#) in the `aws-encryption-sdk-net` directory of the `aws-encryption-sdk-dafny` repository on GitHub.

Encrypting data in the AWS Encryption SDK for .NET

This example shows the basic pattern for encrypting data. It encrypts a small file with data keys that are protected by one AWS KMS wrapping key.

Step 1: Instantiate the AWS Encryption SDK and the material providers library.

Begin by instantiating the AWS Encryption SDK and the material providers library. You'll use the methods in the AWS Encryption SDK to encrypt and decrypt data. You'll use the methods in the material providers library to create the keyrings that specify which keys protect your data.

```
// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();
```

Step 2: Create an input object for the keyring.

Each method that creates a keyring has a corresponding input object class. For example, to create the input object for the `CreateAwsKmsKeyring()` method, create an instance of the `CreateAwsKmsKeyringInput` class.

Even though the input for this keyring doesn't specify a [generator key \(p. 50\)](#), the single KMS key specified by the `KmsKeyId` parameter is the generator key. It generates and encrypts the data key that encrypts the data.

This input object requires an AWS KMS client for the AWS Region of the KMS key. To create a AWS KMS client, instantiate the `AmazonKeyManagementServiceClient` class in the AWS SDK for .NET. Calling the `AmazonKeyManagementServiceClient()` constructor with no parameters creates a client with the default values.

In an AWS KMS keyring used for encrypting with the AWS Encryption SDK for .NET, you can [identify the KMS keys \(p. 50\)](#) by using the key ID, key ARN, alias name, or alias ARN. In an AWS KMS keyring

used for decrypting, you must use a key ARN to identify each KMS key. If you plan to reuse your encryption keyring for decrypting, use a key ARN identifier for all KMS keys.

```
string keyArn = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
// Instantiate the keyring input object  
var kmsKeyringInput = new CreateAwsKmsKeyringInput  
{  
    KmsClient = new AmazonKeyManagementServiceClient(),  
    KmsKeyId = keyArn  
};
```

Step 3: Create the keyring.

To create the keyring, call the keyring method with the keyring input object. This example uses the `CreateAwsKmsKeyring()` method, which takes just one KMS key.

```
var keyring = materialProviders.CreateAwsKmsKeyring(kmsKeyringInput);
```

Step 4: Define an encryption context.

An [encryption context \(p. 8\)](#) is an optional, but strongly recommended element of cryptographic operations in the AWS Encryption SDK. You can define one or more non-secret key-value pairs.

```
// Define the encryption context  
var encryptionContext = new Dictionary<string, string>()  
{  
    {"purpose", "test"}  
};
```

Step 5: Create the input object for encrypting.

Before calling the `Encrypt()` method, create an instance of the `EncryptInput` class.

```
string plaintext = File.ReadAllText("C:\\Documents\\CryptoTest\\TestFile.txt");  
  
// Define the encrypt input  
var encryptInput = new EncryptInput  
{  
    Plaintext = plaintext,  
    Keyring = keyring,  
    EncryptionContext = encryptionContext  
};
```

Step 6: Encrypt the plaintext.

Use the `Encrypt()` method of the AWS Encryption SDK to encrypt the plaintext using the keyring you defined.

The `EncryptOutput` that the `Encrypt()` method returns has methods for getting the encrypted message (`Ciphertext`), encryption context, and algorithm suite.

```
var encryptOutput = encryptionSdk.Encrypt(encryptInput);
```

Step 7: Get the encrypted message.

The `Decrypt()` method in the AWS Encryption SDK for .NET takes the `Ciphertext` member of the `EncryptOutput` instance.

The `Ciphertext` member of the `EncryptOutput` object is the [encrypted message \(p. 8\)](#), a portable object that includes the encrypted data, encrypted data keys, and metadata, including the encryption context. You can safely store the encrypted message for an extended time or submit it to the `Decrypt()` method to recover the plaintext.

```
var encryptedMessage = encryptOutput.Ciphertext;
```

Decrypting in strict mode in the AWS Encryption SDK for .NET

Best practices recommend that you specify the keys that you use to decrypt data, an option known as *strict mode*. The AWS Encryption SDK uses only the KMS keys that you specify in your keyring to decrypt the ciphertext. The keys in your decryption keyring must include at least one of the keys that encrypted the data.

This example shows the basic pattern of decrypting in strict mode with the AWS Encryption SDK for .NET.

Step 1: Instantiate the AWS Encryption SDK and material providers library.

```
// Instantiate the AWS Encryption SDK and material providers
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();
```

Step 2: Create the input object for your keyring.

To specify the parameters for the keyring method, create an input object. Each keyring method in the AWS Encryption SDK for .NET has a corresponding input object. Because this example uses the `CreateAwsKmsKeyring()` method to create the keyring, it instantiates the `CreateAwsKmsKeyringInput` class for the input.

In a decryption keyring, you must use a key ARN to identify KMS keys.

```
string keyArn = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

// Instantiate the keyring input object
var kmsKeyringInput = new CreateAwsKmsKeyringInput
{
    KmsClient = new AmazonKeyManagementServiceClient(),
    KmsKeyId = keyArn
};
```

Step 3: Create the keyring.

To create the decryption keyring, this example uses the `CreateAwsKmsKeyring()` method and the keyring input object.

```
var keyring = materialProviders.CreateAwsKmsKeyring(kmsKeyringInput);
```

Step 4: Create the input object for decrypting.

To create the input object for the `Decrypt()` method, instantiate the `DecryptInput` class.

The `Ciphertext` parameter of the `DecryptInput()` constructor takes the `Ciphertext` member of the `EncryptOutput` object that the `Encrypt()` method returned. The `Ciphertext` property

represents the [encrypted message \(p. 8\)](#), which includes the encrypted data, encrypted data keys, and metadata that the AWS Encryption SDK needs to decrypt the message.

```
var encryptedMessage = encryptOutput.Ciphertext;

var decryptInput = new DecryptInput
{
    Ciphertext = encryptedMessage,
    Keyring = keyring
};
```

Step 5: Decrypt the ciphertext.

```
var decryptOutput = encryptionSdk.Decrypt(decryptInput);
```

Step 6: Verify the encryption context.

The `Decrypt()` method of the AWS Encryption SDK does not take an encryption context. It gets the encryption context values from the metadata in the encrypted message. However, before returning or using the plaintext, it's a best practice to verify that encryption context that was used to decrypt the ciphertext includes the encryption context you provided when encrypting.

Verify that the encryption context used on encrypt *is included* in the encryption context that used to decrypt the ciphertext. The AWS Encryption SDK adds pairs to the encryption context, including the digital signature if you're using an algorithm suite with signing, such as the default algorithm suite.

```
// Verify the encryption context
string contextKey = "purpose";
string contextValue = "test";

if (!decryptOutput.EncryptionContext.TryGetValue(contextKey, out var
    decryptContextValue)
    || !decryptContextValue.Equals(contextValue))
{
    throw new Exception("Encryption context does not match expected values");
}
```

Decrypting with a discovery keyring in the AWS Encryption SDK for .NET

Rather than specifying the KMS keys for decryption, you can provide a AWS KMS *discovery keyring*, which is a keyring that doesn't specify any KMS keys. A discovery keyring lets the AWS Encryption SDK decrypt the data by using whichever KMS key encrypted it, provided that the caller has decrypt permission on the key. For best practices, add a discovery filter that limits the KMS keys that can be used to those in particular AWS accounts of a specified partition.

The AWS Encryption SDK for .NET provides a basic discovery keyring that requires an AWS KMS client and a discovery multi-keyring that requires you to specify one or more AWS Regions. The client and Regions both limit the KMS keys that can be used to decrypt the encrypted message. The input objects for both keyrings take the recommended discovery filter.

The following example shows the pattern for decrypting data with an AWS KMS discovery keyring and discovery filter.

Step 1: Instantiate the AWS Encryption SDK and the material providers library.

```
// Instantiate the AWS Encryption SDK and material providers
```

```
var encryptionSdk = AwsEncryptionSdkFactory.CreateDefaultAwsEncryptionSdk();  
var materialProviders =  
  
    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();
```

Step 2: Create the input object for the keyring.

To specify the parameters for the keyring method, create an input object. Each keyring method in the AWS Encryption SDK for .NET has a corresponding input object. Because this example uses the `CreateAwsKmsDiscoveryKeyring()` method to create the keyring, it instantiates the `CreateAwsKmsDiscoveryKeyringInput` class for the input.

```
List<string> accounts = new List<string> { "111122223333" };  
  
var discoveryKeyringInput = new CreateAwsKmsDiscoveryKeyringInput  
{  
    KmsClient = new AmazonKeyManagementServiceClient(),  
    DiscoveryFilter = new DiscoveryFilter()  
    {  
        AccountIds = accounts,  
        Partition = "aws"  
    }  
};
```

Step 3: Create the keyring.

To create the decryption keyring, this example uses the `CreateAwsKmsDiscoveryKeyring()` method and the keyring input object.

```
var discoveryKeyring =  
    materialProviders.CreateAwsKmsDiscoveryKeyring(discoveryKeyringInput);
```

Step 4: Create the input object for decrypting.

To create the input object for the `Decrypt()` method, instantiate the `DecryptInput` class. The value of the `Ciphertext` parameter is the `Ciphertext` member of the `EncryptOutput` object that the `Encrypt()` method returns.

```
var ciphertext = encryptOutput.Ciphertext;  
  
var decryptInput = new DecryptInput  
{  
    Ciphertext = ciphertext,  
    Keyring = discoveryKeyring  
};  
var decryptOutput = encryptionSdk.Decrypt(decryptInput);
```

Step 5: Verify the encryption context.

The AWS Encryption SDK does not take an encryption context on `Decrypt()`. It gets the encryption context values from the metadata in the encrypted message. However, before returning or using the plaintext, it's a best practice to verify that encryption context that was used to decrypt the ciphertext includes the encryption context you provided when encrypting.

Verify that the encryption context used on encrypt *is included* in the encryption context that was used to decrypt the ciphertext. The AWS Encryption SDK adds pairs to the encryption context, including the digital signature if you're using an algorithm suite with signing, such as the default algorithm suite.

```
// Verify the encryption context
string contextKey = "purpose";
string contextValue = "test";

if (!decryptOutput.EncryptionContext.TryGetValue(contextKey, out var
    decryptContextValue)
    || !decryptContextValue.Equals(contextValue))
{
    throw new Exception("Encryption context does not match expected values");
}
```

AWS Encryption SDK for Java

This topic explains how to install and use the AWS Encryption SDK for Java. For details about programming with the AWS Encryption SDK for Java, see the [aws-encryption-sdk-java](#) repository on GitHub. For API documentation, see the [Javadoc](#) for the AWS Encryption SDK for Java.

Topics

- [Prerequisites](#) (p. 85)
- [Installation](#) (p. 86)
- [AWS Encryption SDK for Java example code](#) (p. 86)

Prerequisites

Before you install the AWS Encryption SDK for Java, be sure you have the following prerequisites.

A Java development environment

You will need Java 8 or later. On the Oracle website, go to [Java SE Downloads](#), and then download and install the Java SE Development Kit (JDK).

If you use the Oracle JDK, you must also download and install the [Java Cryptography Extension \(JCE\) Unlimited Strength Jurisdiction Policy Files](#).

Bouncy Castle

The AWS Encryption SDK for Java requires [Bouncy Castle](#).

- AWS Encryption SDK for Java versions 1.6.1 and later use Bouncy Castle to serialize and deserialize cryptographic objects. You can use Bouncy Castle or [Bouncy Castle FIPS](#) to satisfy this requirement. For help installing and configuring Bouncy Castle FIPS, see [BC FIPS Documentation](#), especially the **User Guides** and **Security Policy** PDFs.
- Earlier versions of the AWS Encryption SDK for Java use Bouncy Castle's cryptography API for Java. This requirement is satisfied only by non-FIPS Bouncy Castle.

If you don't have Bouncy Castle, go to [Bouncy Castle latest releases](#) to download the provider file that corresponds to your JDK. You can also use [Apache Maven](#) to get the artifact for the standard Bouncy Castle provider ([bcprov-ext-jdk15on](#)) or the artifact for Bouncy Castle FIPS ([bc-fips](#)).

AWS SDK for Java (Optional)

The AWS Encryption SDK for Java does not require the AWS SDK for Java. However, the AWS SDK for Java is required to use [AWS Key Management Service](#) (AWS KMS) as a master key provider. It's also required for some of the Java code examples in this guide.

Beginning in the AWS Encryption SDK for Java version 2.4.0, the AWS Encryption SDK for Java supports both version 1.x and 2.x of the AWS SDK for Java. AWS Encryption SDK code for the AWS SDK for Java 1.x and 2.x are interoperable. For example, you can encrypt data with AWS Encryption SDK code that supports AWS SDK for Java 1.x and decrypt it using code that supports AWS SDK for Java 2.x (or vice versa). Versions of the AWS Encryption SDK for Java earlier than 2.4.0 support only AWS SDK for Java 1.x. For information about updating your version of the AWS Encryption SDK, see [Migrating to AWS Encryption SDK Versions 2.0.x and later \(p. 200\)](#).

When updating your AWS Encryption SDK for Java code from the AWS SDK for Java 1.x to AWS SDK for Java 2.x, replace references to the [AWSKMS interface](#) in AWS SDK for Java 1.x with references to the [KmsClient interface](#) in AWS SDK for Java 2.x. Also, update your code to use the AWS KMS-related objects in the `kmssdkv2` namespace, instead of the `kms` namespace.

To install the AWS SDK for Java, use Apache Maven.

- To [import the entire AWS SDK for Java](#) as a dependency, declare it in your `pom.xml` file.
- To create a dependency only for the AWS KMS module in AWS SDK for Java 1.x, follow the instructions for [specifying particular modules](#), and set the `artifactId` to `aws-java-sdk-kms`.
- To create a dependency only for the AWS KMS module in AWS SDK for Java 2.x, follow the instructions for [specifying particular modules](#). Set the `groupId` to `software.amazon.awssdk` and the `artifactId` to `kms`.

For more changes, see [What's different between the AWS SDK for Java 1.x and 2.x](#) in the AWS SDK for Java 2.x Developer Guide.

Java examples in the AWS Encryption SDK Developer Guide use the AWS SDK for Java 2.x.

Installation

You can install the AWS Encryption SDK for Java in the following ways.

Manually

To install the AWS Encryption SDK for Java, clone or download the [aws-encryption-sdk-java](#) GitHub repository.

Using Apache Maven

The AWS Encryption SDK for Java is available through [Apache Maven](#) with the following dependency definition.

```
<dependency>
  <groupId>com.amazonaws</groupId>
  <artifactId>aws-encryption-sdk-java</artifactId>
  <version>2.0.0</version>
</dependency>
```

After you install the SDK, get started by looking at the [example Java code \(p. 86\)](#) in this guide and the [Javadoc on GitHub](#).

AWS Encryption SDK for Java example code

The following examples show you how to use the AWS Encryption SDK for Java to encrypt and decrypt data. These examples show how to use [version 2.0.x \(p. 194\)](#) and later of the AWS Encryption SDK for Java. For examples that use earlier versions, find your release in the [Releases](#) list of the [aws-encryption-sdk-java](#) repository on GitHub.

Java examples in the AWS Encryption SDK Developer Guide use the AWS SDK for Java 2.x.

Topics

- [Encrypting and decrypting strings \(p. 87\)](#)
- [Encrypting and decrypting byte streams \(p. 89\)](#)
- [Encrypting and decrypting byte streams with multiple master key providers \(p. 91\)](#)

Encrypting and decrypting strings

The following example shows you how to use the AWS Encryption SDK for Java to encrypt and decrypt strings. Before using the string, convert it into a byte array.

This example uses an AWS KMS key as the wrapping key. When encrypting, the `KmsMasterKeyProvider buildStrict()` method takes a key ID, key ARN, alias name, or alias ARN. When decrypting, it [requires a key ARN \(p. 20\)](#). In this case, because the `keyArn` parameter is used for encrypting and decrypting, its value must be a key ARN. For information about IDs for AWS KMS keys, see [Key identifiers](#) in the *AWS Key Management Service Developer Guide*.

When you call the `encryptData()` method, it returns an [encrypted message \(p. 8\)](#) (`CryptoResult`) that includes the ciphertext, the encrypted data keys, and the encryption context. When you call `getResult` on the `CryptoResult` object, it returns a base-64-encoded string version of the [encrypted message \(p. 224\)](#) that you can pass to the `decryptData()` method.

Similarly, when you call `decryptData()`, the `CryptoResult` object it returns contains the plaintext message and an AWS KMS key ID. Before your application returns the plaintext, verify that the AWS KMS key ID and the encryption context in the encrypted message are the ones that you expect.

        // This builds the AwsCrypto client with the RequireEncryptRequireDecrypt
        // commitment policy,
        // which enforces that this client only encrypts using committing algorithm suites
        // and enforces
        // that this client will only decrypt encrypted messages that were created with a
        // committing algorithm suite.
        // This is the default commitment policy if you build the client with
        // `AwsCrypto.builder().build()`
        // or `AwsCrypto.standard()`.
        final AwsCrypto crypto = AwsCrypto.builder()
            .withCommitmentPolicy(CommitmentPolicy.RequireEncryptRequireDecrypt)
            .build();

        // 2. Instantiate an AWS KMS master key provider in strict mode using
        // buildStrict().
        // In strict mode, the AWS KMS master key provider encrypts and decrypts only by
        // using the key
        // indicated by keyArn.
        // To encrypt and decrypt with this master key provider, use an AWS KMS key ARN to
        // identify the AWS KMS keys.
        // In strict mode, the decrypt operation requires a key ARN.
        final KmsMasterKeyProvider keyProvider =
            KmsMasterKeyProvider.builder().buildStrict(keyArn);

        // 3. Create an encryption context
        // Most encrypted data should have an associated encryption context
        // to protect integrity. This sample uses placeholder values.
        // For more information see:
        // blogs.aws.amazon.com/security/post/Tx2LZ6WBJJANTNW/How-to-Protect-the-Integrity-
        // of-Your-Encrypted-Data-by-Using-AWS-Key-Management
        final Map<String, String> encryptionContext =
            Collections.singletonMap("ExampleContextKey",
                "ExampleContextValue");

        // 4. Encrypt the data
        final CryptoResult<byte[], KmsMasterKey> encryptResult =
            crypto.encryptData(keyProvider,
                EXAMPLE_DATA, encryptionContext);
        final byte[] ciphertext = encryptResult.getResult();

        // 5. Decrypt the data
        final CryptoResult<byte[], KmsMasterKey> decryptResult =
            crypto.decryptData(keyProvider,
                ciphertext);

        // 6. Verify that the encryption context in the result contains the
        // encryption context supplied to the encryptData method. Because the
        // SDK can add values to the encryption context, don't require that
        // the entire context matches.
        if (!encryptionContext.entrySet().stream()
            .allMatch(
                e ->
                    e.getValue().equals(decryptResult.getEncryptionContext().get(e.getKey())))) {
            throw new IllegalStateException("Wrong Encryption Context!");
        }

        // 7. Verify that the decrypted plaintext matches the original plaintext
        assert Arrays.equals(decryptResult.getResult(), EXAMPLE_DATA);
    }

```

```
}
```

Encrypting and decrypting byte streams

The following example shows you how to use the AWS Encryption SDK to encrypt and decrypt byte streams. This example does not use AWS. It uses the Java Cryptography Extension (JCE) to protect the master key.

When encrypting, this example uses the `AwsCrypto.builder().withEncryptionAlgorithm()` method to specify an algorithm suite without [digital signatures](#) (p. 12). When decrypting, to ensure that the ciphertext is unsigned, this example uses the `createUnsignedMessageDecryptingStream()` method. The `createUnsignedMessageDecryptingStream()` method, introduced in AWS Encryption SDK 1.9.x and 2.2.x, fails if it encounters a ciphertext with a digital signature.

If you're encrypting with the default algorithm suite, which includes digital signatures, use the `createDecryptingStream()` method instead, as shown in the next example.

        commitment policy,
        // which enforces that this client only encrypts using committing algorithm suites
        and enforces
        // that this client will only decrypt encrypted messages that were created with a
        committing algorithm suite.
        // This is the default commitment policy if you build the client with
        `AwsCrypto.builder().build()`
        // or `AwsCrypto.standard()`.
        // This also chooses to encrypt with an algorithm suite that doesn't include
        signing for faster decryption.
        // The use case assumes that the contexts that encrypt and decrypt are equally
        trusted.
        final AwsCrypto crypto = AwsCrypto.builder()
        .withCommitmentPolicy(CommitmentPolicy.RequireEncryptRequireDecrypt)

        .withEncryptionAlgorithm(CryptoAlgorithm.ALG_AES_256_GCM_HKDF_SHA512_COMMIT_KEY)
        .build();

        // Create an encryption context to identify this ciphertext
        Map<String, String> context = Collections.singletonMap("Example",
        "FileStreaming");

        // Because the file might be too large to load into memory, we stream the data,
        instead of
        //loading it all at once.
        FileInputStream in = new FileInputStream(srcFile);
        CryptoInputStream<JceMasterKey> encryptingStream =
        crypto.createEncryptingStream(masterKey, in, context);
        FileOutputStream out = new FileOutputStream(srcFile + ".encrypted");
        IOUtils.copy(encryptingStream, out);
        encryptingStream.close();
        out.close();

        // Decrypt the file. Verify the encryption context before returning the plaintext.
        in = new FileInputStream(srcFile + ".encrypted");
        // Since we encrypted using an unsigned algorithm suite, we can use the
        recommended
        // createUnsignedMessageDecryptingStream method that only accepts unsigned
        messages.
        CryptoInputStream<JceMasterKey> decryptingStream =
        crypto.createUnsignedMessageDecryptingStream(masterKey, in);
        // Does it contain the expected encryption context?
        if
        (!"FileStreaming".equals(decryptingStream.getCryptoResult().getEncryptionContext().get("Example")))
        {
            throw new IllegalStateException("Bad encryption context");
        }

        // Write the plaintext data to disk.
        out = new FileOutputStream(srcFile + ".decrypted");
        IOUtils.copy(decryptingStream, out);
        decryptingStream.close();
        out.close();
    }

    /**

```

```
    * In practice, this key would be saved in a secure location.
    * For this demo, we generate a new random key for each operation.
    */
    private static SecretKey retrieveEncryptionKey() {
        SecureRandom rnd = new SecureRandom();
        byte[] rawKey = new byte[16]; // 128 bits
        rnd.nextBytes(rawKey);
        return new SecretKeySpec(rawKey, "AES");
    }
}
```

Encrypting and decrypting byte streams with multiple master key providers

The following example shows you how to use the AWS Encryption SDK with more than one master key provider. Using more than one master key provider creates redundancy if one master key provider is unavailable for decryption. This example uses an AWS KMS key in [AWS KMS](#) and an RSA key pair as the master keys.

This example encrypts with the [default algorithm suite \(p. 13\)](#), which includes a [digital signature \(p. 12\)](#). When streaming, the AWS Encryption SDK releases plaintext after integrity checks, but before it has verified the digital signature. To avoid using the plaintext until the signature is verified, this example buffers the plaintext, and writes it to disk only when decryption and verification are complete.

```

AWS Encryption SDK for JavaScript

The AWS Encryption SDK for JavaScript is designed to provide a client-side encryption library for developers who are writing web browser applications in JavaScript or web server applications in Node.js.

Like all implementations of the AWS Encryption SDK, the AWS Encryption SDK for JavaScript offers advanced data protection features. These include [envelope encryption](#), [additional authenticated data \(AAD\)](#), and secure, authenticated, symmetric key [algorithm suites](#) (p. 9), such as 256-bit AES-GCM with key derivation and signing.

All language-specific implementations of the AWS Encryption SDK are designed to be interoperable, subject to the constraints of the language. For details about language constraints for JavaScript, see [the section called “Compatibility”](#) (p. 95).

Learn More

- For details about programming with the AWS Encryption SDK for JavaScript, see the [aws-encryption-sdk-javascript](#) repository on GitHub.
- For programming examples, see [the section called “Examples”](#) (p. 99) and the [example-browser](#) and [example-node](#) modules in the [aws-encryption-sdk-javascript](#) repository.
- For a real-world example of using the AWS Encryption SDK for JavaScript to encrypt data in a web application, see [How to enable encryption in a browser with the AWS Encryption SDK for JavaScript and Node.js](#) in the AWS Security Blog.

Topics

- [Compatibility of the AWS Encryption SDK for JavaScript](#) (p. 95)
- [Installing the AWS Encryption SDK for JavaScript](#) (p. 97)
- [Modules in the AWS Encryption SDK for JavaScript](#) (p. 97)
- [AWS Encryption SDK for JavaScript examples](#) (p. 99)

Compatibility of the AWS Encryption SDK for JavaScript

The AWS Encryption SDK for JavaScript is designed to be interoperable with other language implementations of the AWS Encryption SDK. In most cases, you can encrypt data with the AWS Encryption SDK for JavaScript and decrypt it with any other language implementation, including the [AWS Encryption SDK Command Line Interface](#) (p. 112). And you can use the AWS Encryption SDK for JavaScript to decrypt [encrypted messages](#) (p. 8) produced by other language implementations of the AWS Encryption SDK.

However, when you use the AWS Encryption SDK for JavaScript, you need to be aware of some compatibility issues in the JavaScript language implementation and in web browsers.

Also, when using different language implementations, be sure to configure compatible master key providers, master keys, and keyrings. For details, see [Keyring compatibility](#) (p. 47).

AWS Encryption SDK for JavaScript compatibility

The JavaScript implementation of the AWS Encryption SDK differs from other language implementations in the following ways:

- The encrypt operation of the AWS Encryption SDK for JavaScript doesn't return nonframed ciphertext. However, the AWS Encryption SDK for JavaScript will decrypt framed and nonframed ciphertext returned by other language implementations of the AWS Encryption SDK.
- Beginning in Node.js version 12.9.0, Node.js supports the following RSA key wrapping options:
 - OAEP with SHA1, SHA256, SHA384, or SHA512
 - OAEP with SHA1 and MGF1 with SHA1
 - PKCS1v15
- Before version 12.9.0, Node.js supports only the following RSA key wrapping options:
 - OAEP with SHA1 and MGF1 with SHA1
 - PKCS1v15

Browser compatibility

Some web browsers don't support basic cryptographic operations that the AWS Encryption SDK for JavaScript requires. You can compensate for some of the missing operations by configuring a fallback for the WebCrypto API that the browser implements.

Web browser limitations

The following limitations are common to all web browsers:

- The WebCrypto API doesn't support PKCS1v15 key wrapping.
- Browsers don't support 192-bit keys.

Required cryptographic operations

The AWS Encryption SDK for JavaScript requires the following operations in web browsers. If a browser doesn't support these operations, it's incompatible with the AWS Encryption SDK for JavaScript.

- The browser must include `crypto.getRandomValues()`, which is a method for generating cryptographically random values. For information about the web browser versions that support `crypto.getRandomValues()`, see [Can I Use crypto.getRandomValues\(\)](#)?

Required fallback

The AWS Encryption SDK for JavaScript requires the following libraries and operations in web browsers. If you support a web browser that doesn't fulfill these requirements, you must configure a fallback. Otherwise, attempts to use the AWS Encryption SDK for JavaScript with the browser will fail.

- The WebCrypto API, which performs basic cryptographic operations in web applications, isn't available for all browsers. For information about the web browser versions that support web cryptography, see [Can I Use Web Cryptography?](#).
- Modern versions of the Safari web browser don't support AES-GCM encryption of zero bytes, which the AWS Encryption SDK requires. If the browser implements the WebCrypto API, but can't use AES-GCM to encrypt zero bytes, the AWS Encryption SDK for JavaScript uses the fallback library only for zero-byte encryption. It uses the WebCrypto API for all other operations.

To configure a fallback for either limitation, add the following statements to your code. In the [configureFallback](#) function, specify a library that supports the missing features. The following example uses the Microsoft Research JavaScript Cryptography Library (`msrcrypto`), but you can replace it with a compatible library. For a complete example, see [fallback.ts](#).

```
import { configureFallback } from '@aws-crypto/client-browser'
```

```
configureFallback(msrCrypto)
```

Installing the AWS Encryption SDK for JavaScript

The AWS Encryption SDK for JavaScript consists of a collection of interdependent modules. Several of the modules are just collections of modules that are designed to work together. Some modules are designed to work independently. A few modules are required for all implementations; a few others are required only for special cases. For information about the modules in the AWS Encryption SDK for JavaScript, see [Modules in the AWS Encryption SDK for JavaScript \(p. 97\)](#) and the `README.md` file in each of the modules in the [aws-encryption-sdk-javascript](#) repository on GitHub.

To install the modules, use the [npm package manager](#).

For example, to install the `client-node` module, which includes all of the modules you need to program with the AWS Encryption SDK for JavaScript in Node.js, use the following command.

```
npm install @aws-crypto/client-node
```

To install the `client-browser` module, which includes all of the modules you need to program with the AWS Encryption SDK for JavaScript in the browser, use the following command.

```
npm install @aws-crypto/client-browser
```

For working examples of how to use the AWS Encryption SDK for JavaScript, see the examples in the `example-node` and `example-browser` modules in the [aws-encryption-sdk-javascript](#) repository on GitHub.

Modules in the AWS Encryption SDK for JavaScript

The modules in the AWS Encryption SDK for JavaScript make it easy to install the code that you need for your projects.

Modules for JavaScript Node.js

[client-node](#)

Includes all of the modules you need to program with the AWS Encryption SDK for JavaScript in Node.js.

[caching-materials-manager-node](#)

Exports functions that support the [data key caching \(p. 152\)](#) feature in the AWS Encryption SDK for JavaScript in Node.js.

[decrypt-node](#)

Exports functions that decrypt and verify encrypted messages representing data and data streams. Included in the `client-node` module.

[encrypt-node](#)

Exports functions that encrypt and sign different types of data. Included in the `client-node` module.

[example-node](#)

Exports working examples of programming with the AWS Encryption SDK for JavaScript in Node.js. Includes example of different types of keyrings and different types of data.

hkdf-node

Exports an [HMAC-based Key Derivation Function \(HKDF\)](#) that the AWS Encryption SDK for JavaScript in Node.js uses in particular algorithm suites. The AWS Encryption SDK for JavaScript in the browser uses the native HKDF function in the WebCrypto API.

integration-node

Defines tests that verify that the AWS Encryption SDK for JavaScript in Node.js is compatible with other language implementations of the AWS Encryption SDK.

kms-keyring-node

Exports functions that support AWS KMS keyrings in Node.js.

raw-aes-keyring-node

Exports functions that support [Raw AES keyrings \(p. 59\)](#) in Node.js.

raw-rsa-keyring-node

Exports functions that support [Raw RSA keyrings \(p. 61\)](#) in Node.js.

Modules for JavaScript Browser

client-browser

Includes all of the modules you need to program with the AWS Encryption SDK for JavaScript in the browser.

caching-materials-manager-browser

Exports functions that support the [data key caching \(p. 152\)](#) feature for JavaScript in the browser.

decrypt-browser

Exports functions that decrypt and verify encrypted messages representing data and data streams.

encrypt-browser

Exports functions that encrypt and sign different types of data.

example-browser

Working examples of programming with the AWS Encryption SDK for JavaScript in the browser. Includes examples of different types of keyrings and different types of data.

integration-browser

Defines tests that verify that the AWS Encryption SDK for JavaScript in the browser is compatible with other language implementations of the AWS Encryption SDK.

kms-keyring-browser

Exports functions that support [AWS KMS keyrings \(p. 49\)](#) in the browser.

raw-aes-keyring-browser

Exports functions that support [Raw AES keyrings \(p. 59\)](#) in the browser.

raw-rsa-keyring-browser

Exports functions that support [Raw RSA keyrings \(p. 61\)](#) in the browser.

Modules for all implementations

[cache-material](#)

Supports the [data key caching \(p. 152\)](#) feature. Provides code for assembling the cryptographic materials that are cached with each data key.

[kms-keyring](#)

Exports functions that support [KMS keyrings \(p. 49\)](#).

[material-management](#)

Implements the [cryptographic materials manager \(p. 9\)](#) (CMM).

[raw-keyring](#)

Exports functions required for raw AES and RSA keyrings.

[serialize](#)

Exports functions that the SDK uses to serialize its output.

[web-crypto-backend](#)

Exports functions that use the WebCrypto API in the AWS Encryption SDK for JavaScript in the browser.

AWS Encryption SDK for JavaScript examples

The following examples show you how to use the AWS Encryption SDK for JavaScript to encrypt and decrypt data.

You can find more examples of using the AWS Encryption SDK for JavaScript in the [example-node](#) and [example-browser](#) modules in the [aws-encryption-sdk-javascript](#) repository on GitHub. These example modules are not installed when you install the `client-browser` or `client-node` modules.

See the complete code samples: Node: [kms_simple.ts](#), Browser: [kms_simple.ts](#)

Topics

- [Encrypting data with an AWS KMS keyring \(p. 99\)](#)
- [Decrypting data with an AWS KMS keyring \(p. 101\)](#)

Encrypting data with an AWS KMS keyring

The following example shows you how to use the AWS Encryption SDK for JavaScript to encrypt and decrypt a short string or byte array.

This example features an [AWS KMS keyring \(p. 49\)](#), a type of keyring that uses an AWS KMS key to generate and encrypt data keys. For help creating an AWS KMS key, see [Creating Keys](#) in the *AWS Key Management Service Developer Guide*. For help identifying the AWS KMS keys in an AWS KMS keyring, see [Identifying AWS KMS keys in an AWS KMS keyring \(p. 50\)](#)

Step 1: Construct the keyring.

Create an AWS KMS keyring for encryption.

When encrypting with an AWS KMS keyring, you must specify a *generator key*, that is, an AWS KMS key that is used to generate the plaintext data key and encrypt it. You can also specify zero or more

additional keys that encrypt the same plaintext data key. The keyring returns the plaintext data key and one encrypted copy of that data key for each AWS KMS key in the keyring, including the generator key. To decrypt the data, you need to decrypt any one of the encrypted data keys.

To specify the AWS KMS keys for an encryption keyring in the AWS Encryption SDK for JavaScript, you can use [any supported AWS KMS key identifier \(p. 50\)](#). This example uses a generator key, which is identified by its [alias ARN](#), and one additional key, which is identified by a [key ARN](#).

Note

If you plan to reuse your AWS KMS keyring for decrypting, you must use key ARNs to identify the AWS KMS keys in the keyring.

Before running this code, replace the example AWS KMS key identifiers with valid identifiers. You must have the [permissions required to use the AWS KMS keys \(p. 49\)](#) in the keyring.

JavaScript Browser

Begin by providing your credentials to the browser. The AWS Encryption SDK for JavaScript examples use the [webpack.DefinePlugin](#), which replaces the credential constants with your actual credentials. But you can use any method to provide your credentials. Then, use the credentials to create an AWS KMS client.

```
declare const credentials: {accessKeyId: string, secretAccessKey:string,
  sessionToken:string }

const clientProvider = getClient(KMS, {
  credentials: {
    accessKeyId,
    secretAccessKey,
    sessionToken
  }
})
```

Next, specify the AWS KMS keys for the generator key and additional key. Then, create an AWS KMS keyring using the AWS KMS client and the AWS KMS keys.

```
const generatorKeyId = 'arn:aws:kms:us-west-2:111122223333:alias/EncryptDecrypt'
const keyIds = ['arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab']

const keyring = new KmsKeyringBrowser({ clientProvider, generatorKeyId, keyIds })
```

JavaScript Node.js

```
const generatorKeyId = 'arn:aws:kms:us-west-2:111122223333:alias/EncryptDecrypt'
const keyIds = ['arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab']

const keyring = new KmsKeyringNode({ generatorKeyId, keyIds })
```

Step 2: Set the encryption context.

An [encryption context \(p. 8\)](#) is arbitrary, non-secret additional authenticated data. When you provide an encryption context on encrypt, the AWS Encryption SDK cryptographically binds the encryption context to the ciphertext so that the same encryption context is required to decrypt the data. Using an encryption context is optional, but we recommend it as a best practice.

Create a simple object that includes the encryption context pairs. The key and value in each pair must be a string.

JavaScript Browser

```
const context = {  
  stage: 'demo',  
  purpose: 'simple demonstration app',  
  origin: 'us-west-2'  
}
```

JavaScript Node.js

```
const context = {  
  stage: 'demo',  
  purpose: 'simple demonstration app',  
  origin: 'us-west-2'  
}
```

Step 3: Encrypt the data.

To encrypt the plaintext data, call the `encrypt` function. Pass in the AWS KMS keyring, the plaintext data, and the encryption context.

The `encrypt` function returns an [encrypted message \(p. 8\)](#) (`result`) that contains the encrypted data, the encrypted data keys, and important metadata, including the encryption context and signature.

You can [decrypt this encrypted message \(p. 101\)](#) by using the AWS Encryption SDK for any supported programming language.

JavaScript Browser

```
const plaintext = new Uint8Array([1, 2, 3, 4, 5])  
  
const { result } = await encrypt(keyring, plaintext, { encryptionContext:  
  context })
```

JavaScript Node.js

```
const plaintext = 'asdf'  
  
const { result } = await encrypt(keyring, plaintext, { encryptionContext:  
  context })
```

Decrypting data with an AWS KMS keyring

You can use the AWS Encryption SDK for JavaScript to decrypt the encrypted message and recover the original data.

In this example, we decrypt the data that we encrypted in the [the section called “Encrypting data with an AWS KMS keyring” \(p. 99\)](#) example.

Step 1: Construct the keyring.

To decrypt the data, pass in the [encrypted message \(p. 8\)](#) (`result`) that the `encrypt` function returned. The encrypted message includes the encrypted data, the encrypted data keys, and important metadata, including the encryption context and signature.

You must also specify an [AWS KMS keyring \(p. 49\)](#) when decrypting. You can use the same keyring that was used to encrypt the data or a different keyring. To succeed, at least one AWS KMS key in

the decryption keyring must be able to decrypt one of the encrypted data keys in the encrypted message. Because no data keys are generated, you do not need to specify a generator key in a decryption keyring. If you do, the generator key and additional keys are treated the same way.

To specify an AWS KMS key for a decryption keyring in the AWS Encryption SDK for JavaScript, you must use the [key ARN](#). Otherwise, the AWS KMS key is not recognized. For help identifying the AWS KMS keys in an AWS KMS keyring, see [Identifying AWS KMS keys in an AWS KMS keyring \(p. 50\)](#)

Note

If you use the same keyring for encrypting and decrypting, use key ARNs to identify the AWS KMS keys in the keyring.

In this example, we create a keyring that includes only one of the AWS KMS keys in the encryption keyring. Before running this code, replace the example key ARN with a valid one. You must have `kms:Decrypt` permission on the AWS KMS key.

JavaScript Browser

Begin by providing your credentials to the browser. The AWS Encryption SDK for JavaScript examples use the [webpack.DefinePlugin](#), which replaces the credential constants with your actual credentials. But you can use any method to provide your credentials. Then, use the credentials to create an AWS KMS client.

```
declare const credentials: {accessKeyId: string, secretAccessKey:string,
  sessionToken:string }

const clientProvider = getClient(KMS, {
  credentials: {
    accessKeyId,
    secretAccessKey,
    sessionToken
  }
})
```

Next, create an AWS KMS keyring using the AWS KMS client. This example uses just one of the AWS KMS keys from the encryption keyring.

```
const keyIds = ['arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab']

const keyring = new KmsKeyringBrowser({ clientProvider, keyIds })
```

JavaScript Node.js

```
const keyIds = ['arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab']

const keyring = new KmsKeyringNode({ keyIds })
```

Step 2: Decrypt the data.

Next, call the `decrypt` function. Pass in the decryption keyring that you just created (`keyring`) and the [encrypted message \(p. 8\)](#) that the `encrypt` function returned (`result`). The AWS Encryption SDK uses the keyring to decrypt one of the encrypted data keys. Then it uses the plaintext data key to decrypt the data.

If the call succeeds, the `plaintext` field contains the plaintext (decrypted) data. The `messageHeader` field contains metadata about the decryption process, including the encryption context that was used to decrypt the data.

JavaScript Browser

```
const { plaintext, messageHeader } = await decrypt(keyring, result)
```

JavaScript Node.js

```
const { plaintext, messageHeader } = await decrypt(keyring, result)
```

Step 3: Verify the encryption context.

The [encryption context \(p. 8\)](#) that was used to decrypt the data is included in the message header (`messageHeader`) that the `decrypt` function returns. Before your application returns the plaintext data, verify that the encryption context that you provided when encrypting is included in the encryption context that was used when decrypting. A mismatch might indicate that the data was tampered with, or that you didn't decrypt the right ciphertext.

When verifying the encryption context, do not require an exact match. When you use an encryption algorithm with signing, the [cryptographic materials manager \(p. 9\)](#) (CMM) adds the public signing key to the encryption context before encrypting the message. But all of the encryption context pairs that you submitted should be included in the encryption context that was returned.

First, get the encryption context from the message header. Then, verify that each key-value pair in the original encryption context (`context`) matches a key-value pair in the returned encryption context (`encryptionContext`).

JavaScript Browser

```
const { encryptionContext } = messageHeader

Object
  .entries(context)
  .forEach(([key, value]) => {
    if (encryptionContext[key] !== value) throw new Error('Encryption Context does
    not match expected values')
  })
```

JavaScript Node.js

```
const { encryptionContext } = messageHeader

Object
  .entries(context)
  .forEach(([key, value]) => {
    if (encryptionContext[key] !== value) throw new Error('Encryption Context does
    not match expected values')
  })
```

If the encryption context check succeeds, you can return the plaintext data.

AWS Encryption SDK for Python

This topic explains how to install and use the AWS Encryption SDK for Python. For details about programming with the AWS Encryption SDK for Python, see the [aws-encryption-sdk-python](#) repository on GitHub. For API documentation, see [Read the Docs](#).

Topics

- [Prerequisites](#) (p. 104)
- [Installation](#) (p. 104)
- [AWS Encryption SDK for Python example code](#) (p. 104)

Prerequisites

Before you install the AWS Encryption SDK for Python, be sure you have the following prerequisites.

A supported version of Python

Python 3.6 or later is required by the AWS Encryption SDK for Python versions 3.1.0 and later.

Earlier versions of the AWS Encryption SDK support Python 2.7 and Python 3.4 and later, but we recommend that you use the latest version of the AWS Encryption SDK.

To download Python, see [Python downloads](#).

The pip installation tool for Python

pip is included in Python 3.6 and later versions, although you might want to upgrade it. For more information about upgrading or installing pip, see [Installation](#) in the pip documentation.

Installation

Use pip to install the AWS Encryption SDK for Python, as shown in the following examples.

To install the latest version

```
pip install aws-encryption-sdk
```

For more details about using pip to install and upgrade packages, see [Installing Packages](#).

The SDK requires the [cryptography library](#) on all platforms. All versions of pip install and build the **cryptography** library on Windows. pip 8.1 and later installs and builds **cryptography** on Linux. If you are using an earlier version of pip and your Linux environment doesn't have the tools needed to build the **cryptography** library, you need to install them. For more information, see [Building Cryptography on Linux](#).

For the latest development version of this SDK, go to the [aws-encryption-sdk-python GitHub repository](#).

After you install the SDK, get started by looking at the [example Python code](#) (p. 104) in this guide.

AWS Encryption SDK for Python example code

The following examples show you how to use the AWS Encryption SDK for Python to encrypt and decrypt data.

The examples in this section show how to use [version 2.0.x](#) (p. 194) and later of the AWS Encryption SDK for Python. For examples that use earlier versions, find your release in the [Releases](#) list of the [aws-encryption-sdk-python](#) repository on GitHub.

Topics

- [Encrypting and decrypting strings](#) (p. 105)

- [Encrypting and decrypting byte streams \(p. 106\)](#)
- [Encrypting and decrypting byte streams with multiple master key providers \(p. 108\)](#)
- [Using data key caching to encrypt messages \(p. 110\)](#)

Encrypting and decrypting strings

The following example shows you how to use the AWS Encryption SDK to encrypt and decrypt strings. This example uses an AWS KMS key in [AWS Key Management Service \(AWS KMS\)](#) as the master key.

When encrypting, the `StrictAwsKmsMasterKeyProvider` constructor takes a key ID, key ARN, alias name, or alias ARN. When decrypting, it [requires a key ARN \(p. 20\)](#). In this case, because the `keyArn` parameter is used for encrypting and decrypting, its value must be a key ARN. For information about IDs for AWS KMS keys, see [Key identifiers](#) in the *AWS Key Management Service Developer Guide*.

"""Example showing basic encryption and decryption of a value already in memory."""
import aws_encryption_sdk
from aws_encryption_sdk import CommitmentPolicy

def cycle_string(key_arn, source_plaintext, botocore_session=None):
    """Encrypts and then decrypts a string under an AWS KMS key.

    :param str key_arn: Amazon Resource Name (ARN) of the AWS KMS key
    :param bytes source_plaintext: Data to encrypt
    :param botocore_session: existing botocore session instance
    :type botocore_session: botocore.session.Session
    """
    # Set up an encryption client with an explicit commitment policy. If you do not
    # explicitly choose a
    # commitment policy, REQUIRE_ENCRYPT_REQUIRE_DECRYPT is used by default.
    client =
aws_encryption_sdk.EncryptionSDKClient(commitment_policy=CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT)

    # Create an AWS KMS master key provider
    kms_kwargs = dict(key_ids=[key_arn])
    if botocore_session is not None:
        kms_kwargs["botocore_session"] = botocore_session
    master_key_provider = aws_encryption_sdk.StrictAwsKmsMasterKeyProvider(**kms_kwargs)

    # Encrypt the plaintext source data
    ciphertext, encryptor_header = client.encrypt(source=source_plaintext,
key_provider=master_key_provider)

    # Decrypt the ciphertext
    cycled_plaintext, decrypt_header = client.decrypt(source=ciphertext,
key_provider=master_key_provider)

    # Verify that the "cycled" (encrypted, then decrypted) plaintext is identical to the
    source plaintext
```

```
assert cycled_plaintext == source_plaintext

# Verify that the encryption context used in the decrypt operation includes all key
pairs from
# the encrypt operation. (The SDK can add pairs, so don't require an exact match.)
#
# In production, always use a meaningful encryption context. In this sample, we omit
the
# encryption context (no key pairs).
assert all(
    pair in decrypted_header.encryption_context.items() for pair in
encryptor_header.encryption_context.items()
)
```

Encrypting and decrypting byte streams

The following example shows you how to use the AWS Encryption SDK to encrypt and decrypt byte streams. This example doesn't use AWS. It uses a static, ephemeral master key provider.

When encrypting, this example uses an alternate algorithm suite without [digital signatures \(p. 12\)](#) (AES_256_GCM_HKDF_SHA512_COMMIT_KEY). This algorithm suite is appropriate when the users who are encrypting and decrypting data are equally trusted. Then, when decrypting, the example uses the decrypt-unsigned streaming mode, which fails if it encounters signed ciphertext. The decrypt-unsigned streaming mode is introduced in AWS Encryption SDK versions 1.9.x and 2.2.x.

)
return ciphertext_filename, cycled_plaintext_filename
```

Encrypting and decrypting byte streams with multiple master key providers

The following example shows you how to use the AWS Encryption SDK with more than one master key provider. Using more than one master key provider creates redundancy if one master key provider is unavailable for decryption. This example uses an AWS KMS key and an RSA key pair as the master keys.

This example encrypts with the [default algorithm suite \(p. 13\)](#), which includes a [digital signature \(p. 12\)](#). When streaming, the AWS Encryption SDK releases plaintext after integrity checks, but before it has verified the digital signature. To avoid using the plaintext until the signature is verified, this example buffers the plaintext, and writes it to disk only when decryption and verification are complete.

Using data key caching to encrypt messages

The following example shows how to use [data key caching](#) (p. 152) in the AWS Encryption SDK for Python. It is designed to show you how to configure an instance of the [local cache](#) (p. 172) (LocalCryptoMaterialsCache) with the required capacity value and an instance of the [caching cryptographic materials manager](#) (p. 172) (caching CMM) with [cache security thresholds](#) (p. 168).

This very basic example creates a function that encrypts a fixed string. It lets you specify an AWS KMS key, the required cache size (capacity), and a maximum age value. For a more complex, real-world example of data key caching, see [Data key caching example code](#) (p. 176).

Although it is optional, this example also uses an [encryption context](#) (p. 8) as additional authenticated data. When you decrypt data that was encrypted with an encryption context, be sure that your

application verifies that the encryption context is the one that you expect before returning the plaintext data to your caller. An encryption context is a best practice element of any encryption or decryption operation, but it plays a special role in data key caching. For details, see [Encryption Context: How to Select Cache Entries \(p. 173\)](#).

    # in the caching CMM
    encrypted_message, _header = client.encrypt(
        source=my_data, materials_manager=caching_cmm,
        encryption_context=encryption_context
```

```
)  
  
return encrypted_message
```

AWS Encryption SDK command line interface

The AWS Encryption SDK Command Line Interface (AWS Encryption CLI) enables you to use the AWS Encryption SDK to encrypt and decrypt data interactively at the command line and in scripts. You don't need cryptography or programming expertise.

Note

Version 2.1.x of the AWS Encryption CLI introduces new security features to support [AWS Encryption SDK best practices \(p. 17\)](#). However, version 2.1.x is not backward-compatible; it will cause commands and scripts designed for earlier versions of the AWS Encryption CLI to fail. To mitigate the effect of these changes, we provide a transition version, 1.8.x.

For information about the changes and for help migrating from your current version to version 1.8.x and 2.1.x, see [Migrating to versions 2.0.x and later \(p. 200\)](#).

New security features were originally released in AWS Encryption CLI versions 1.7.x and 2.0.x. However, AWS Encryption CLI version 1.8.x replaces version 1.7.x and AWS Encryption CLI 2.1.x replaces 2.0.x. For details, see the relevant [security advisory](#) in the [aws-encryption-sdk-cli](#) repository on GitHub.

Like all implementations of the AWS Encryption SDK, the AWS Encryption CLI offers advanced data protection features. These include [envelope encryption](#), additional authenticated data (AAD), and secure, authenticated, symmetric key [algorithm suites](#), such as 256-bit AES-GCM with key derivation, [key commitment \(p. 10\)](#), and signing.

The AWS Encryption CLI is built on the [AWS Encryption SDK for Python \(p. 103\)](#) and is supported on Linux, macOS, and Windows. You can run commands and scripts to encrypt and decrypt your data in your preferred shell on Linux or macOS, in a Command Prompt window (cmd.exe) on Windows, and in a PowerShell console on any system.

All language-specific implementations of the AWS Encryption SDK, including the AWS Encryption CLI, are interoperable. For example, you can encrypt data with the [AWS Encryption SDK for Java \(p. 85\)](#) and decrypt it with the AWS Encryption CLI.

This topic introduces the AWS Encryption CLI, explains how to install and use it, and provides several examples to help you get started. For a quick start, see [How to Encrypt and Decrypt Your Data with the AWS Encryption CLI](#) in the AWS Security Blog. For more detailed information, see [Read The Docs](#), and join us in developing the AWS Encryption CLI in the [aws-encryption-sdk-cli](#) repository on GitHub.

Performance

The AWS Encryption CLI is built on the AWS Encryption SDK for Python. Each time you run the CLI, you start a new instance of the Python runtime. To improve performance, whenever possible, use a single command instead of a series of independent commands. For example, run one command that processes the files in a directory recursively instead of running separate commands for each file.

Installing the AWS Encryption SDK command line interface

This topic explains how to install the AWS Encryption CLI. For detailed information, see the [aws-encryption-sdk-cli](#) repository on GitHub and [Read the Docs](#).

Topics

- [Installing the prerequisites \(p. 113\)](#)
- [Installing the AWS Encryption CLI \(p. 114\)](#)

Installing the prerequisites

The AWS Encryption CLI is built on the AWS Encryption SDK for Python. To install the AWS Encryption CLI, you need Python and `pip`, the Python package management tool. Python and `pip` are available on all supported platforms.

Install the following prerequisites before you install the AWS Encryption CLI,

Python

Python 3.6 or later is required by the AWS Encryption CLI versions 4.1.0 and later.

Earlier versions of the AWS Encryption CLI support Python 2.7 and 3.4 and later, but we recommend that you use the latest version of the AWS Encryption CLI.

Python is included in most Linux and macOS installations, but you need to upgrade to Python 3.6 or later. We recommend that you use the latest version of Python. On Windows, you have to install Python; it is not installed by default. To download and install Python, see [Python downloads](#).

To determine whether Python is installed, at the command line, type the following.

```
python
```

To check the Python version, use the `-v` (uppercase V) parameter.

```
python -v
```

On Windows, after you install Python, add the path to the `Python.exe` file to the value of the **Path** environment variable.

By default, Python is installed in the all users directory or in a user profile directory (`%home` or `%userprofile%`) in the `AppData\Local\Programs\Python` subdirectory. To find the location of the `Python.exe` file on your system, check one of the following registry keys. You can use PowerShell to search the registry.

```
PS C:\> dir HKLM:\Software\Python\PythonCore\version\InstallPath
# -or-
PS C:\> dir HKCU:\Software\Python\PythonCore\version\InstallPath
```

pip

`pip` is the Python package manager. To install the AWS Encryption CLI and its dependencies, you need `pip` 8.1 or later. For help installing or upgrading `pip`, see [Installation](#) in the `pip` documentation.

On Linux installations, versions of `pip` earlier than 8.1 can't build the **cryptography** library that the AWS Encryption CLI requires. If you choose not to update your `pip` version, you can install the build tools separately. For more information, see [Building cryptography on Linux](#).

AWS Command Line Interface

The AWS Command Line Interface (AWS CLI) is required only if you are using AWS KMS keys in AWS Key Management Service (AWS KMS) with the AWS Encryption CLI. If you are using a different [master key provider](#) (p. 7), the AWS CLI is not required.

To use AWS KMS keys with the AWS Encryption CLI, you need to [install](#) and [configure](#) the AWS CLI. The configuration makes the credentials that you use to authenticate to AWS KMS available to the AWS Encryption CLI.

Installing the AWS Encryption CLI

When you use `pip` to install the AWS Encryption CLI, it automatically installs the libraries that the CLI needs, including the [AWS Encryption SDK for Python](#) (p. 103), the Python [cryptography library](#), and the [AWS SDK for Python \(Boto3\)](#).

Note

If you are new to the AWS Encryption CLI, install the latest available version.

If you support commands and scripts designed for version of the AWS Encryption CLI before 1.8.x, we recommend that you upgrade first to version 1.8.x before upgrading to version 2.1.x or later. Version 2.1.x of the AWS Encryption CLI introduces new security features to support [AWS Encryption SDK best practices](#) (p. 17). However, version 2.1.x is not backward-compatible; it will cause scripts designed for earlier versions of the AWS Encryption CLI to fail.

New security features were originally released in AWS Encryption CLI versions 1.7.x and 2.0.x.

However, AWS Encryption CLI version 1.8.x replaces version 1.7.x and AWS Encryption CLI 2.1.x replaces 2.0.x. For details, see the relevant [security advisory](#) in the [aws-encryption-sdk-cli](#) repository on GitHub.

For information about the changes and for help migrating from your current version to version 1.8.x and 2.1.x, see [Migrating to versions 2.0.x and later](#) (p. 200).

To install the latest version of the AWS Encryption CLI

```
pip install aws-encryption-sdk-cli
```

To upgrade to the latest version of the AWS Encryption CLI

```
pip install --upgrade aws-encryption-sdk-cli
```

To find the version numbers of your AWS Encryption CLI and AWS Encryption SDK

```
aws-encryption-cli --version
```

The output lists the version numbers of both libraries.

```
aws-encryption-sdk-cli/2.1.0 aws-encryption-sdk/2.0.0
```

To upgrade to the latest version of the AWS Encryption CLI

```
pip install --upgrade aws-encryption-sdk-cli
```

Installing the AWS Encryption CLI also installs the latest version of the AWS SDK for Python (Boto3), if it's not already installed. If Boto3 is installed, the installer verifies the Boto3 version and updates it if required.

To find your installed version of Boto3

```
pip show boto3
```

To update to the latest version of Boto3

```
pip install --upgrade boto3
```

To install the version of the AWS Encryption CLI currently in development, see the [aws-encryption-sdk-cli](#) repository on GitHub.

For more details about using `pip` to install and upgrade Python packages, see the [pip documentation](#).

How to use the AWS Encryption CLI

This topic explains how to use the parameters in the AWS Encryption CLI. For examples, see [Examples of the AWS Encryption CLI](#) (p. 124). For complete documentation, see [Read the Docs](#). The syntax shown in these examples is for AWS Encryption CLI version 2.1.x and later.

Note

Version 2.1.x of the AWS Encryption CLI introduces new security features to support [AWS Encryption SDK best practices](#) (p. 17). However, version 2.1.x is not backward-compatible; it will cause commands and scripts designed for earlier versions of the AWS Encryption CLI to fail. To mitigate the effect of these changes, we provide a transition version, 1.8.x.

For information about the changes and for help migrating from your current version to version 1.8.x and 2.1.x, see [Migrating to versions 2.0.x and later](#) (p. 200).

New security features were originally released in AWS Encryption CLI versions 1.7.x and 2.0.x. However, AWS Encryption CLI version 1.8.x replaces version 1.7.x and AWS Encryption CLI 2.1.x replaces 2.0.x. For details, see the relevant [security advisory](#) in the [aws-encryption-sdk-cli](#) repository on GitHub.

For an example showing how to use the security feature that limits encrypted data keys, see [Limit encrypted data keys](#) (p. 41).

For an example showing how to use AWS KMS multi-Region keys, see [Use multi-Region AWS KMS keys](#) (p. 21).

Topics

- [How to provide input](#) (p. 120)
- [How to specify the output location](#) (p. 121)
- [How to use an encryption context](#) (p. 121)
- [How to specify a commitment policy](#) (p. 123)
- [How to store parameters in a configuration file](#) (p. 123)

How to encrypt and decrypt data

The AWS Encryption CLI uses the features of the AWS Encryption SDK to make it easy to encrypt and decrypt data securely.

Note

The `--master-keys` parameter is deprecated in version 1.8.x of the AWS Encryption CLI and removed in version 2.1.x. Instead, use the `--wrapping-keys` parameter. Beginning in version 2.1.x, the `--wrapping-keys` parameter is required when encrypting and decrypting. For details, see [AWS Encryption SDK CLI syntax and parameter reference \(p. 140\)](#).

- When you encrypt data in the AWS Encryption CLI, you specify your plaintext data and a [wrapping key \(p. 7\)](#) (or *master key*), such as an AWS KMS key in AWS Key Management Service (AWS KMS). If you are using a custom master key provider, you also need to specify the provider. You also specify output locations for the [encrypted message \(p. 8\)](#) and for metadata about the encryption operation. An [encryption context \(p. 8\)](#) is optional, but recommended.

In version 1.8.x, the `--commitment-policy` parameter is required when you use the `--wrapping-keys` parameter; otherwise it's not valid. Beginning in version 2.1.x, the `--commitment-policy` parameter is optional, but recommended.

```
aws-encryption-cli --encrypt --input myPlaintextData \  
  --wrapping-keys key=1234abcd-12ab-34cd-56ef-1234567890ab \  
  --output myEncryptedMessage \  
  --metadata-output ~/metadata \  
  --encryption-context purpose=test \  
  --commitment-policy require-encrypt-require-decrypt
```

The AWS Encryption CLI encrypts your data under a unique data key. Then it encrypts the data key under the wrapping keys you specify. It returns an [encrypted message \(p. 8\)](#) and metadata about the operation. The encrypted message contains your encrypted data (*ciphertext*) and an encrypted copy of the data key. You don't have to worry about storing, managing, or losing the data key.

- When you decrypt data, you pass in your encrypted message, the optional encryption context, and location for the plaintext output and the metadata. You also specify the wrapping keys that the AWS Encryption CLI can use to decrypt the message, or tell the AWS Encryption CLI it can use any wrapping keys that encrypted the message.

Beginning in version 1.8.x, the `--wrapping-keys` parameter is optional when decrypting, but recommended. Beginning in version 2.1.x, the `--wrapping-keys` parameter is required when encrypting and decrypting.

When decrypting, you can use the **key** attribute of the `--wrapping-keys` parameter to specify the wrapping keys that decrypt your data. Specifying an AWS KMS wrapping key when decrypting is optional, but it's a [best practice \(p. 17\)](#) that prevents you from using a key you didn't intend to use. If you're using a custom master key provider, you must specify the provider and wrapping key.

If you don't use the **key** attribute, you must set the [discovery attribute \(p. 118\)](#) of the `--wrapping-keys` parameter to `true`, which lets the AWS Encryption CLI decrypt using any wrapping key that encrypted the message.

As a best practice, use the `--max-encrypted-data-keys` parameter to avoid decrypting a malformed message with an excessive number of encrypted data keys. Specify the expected number of encrypted data keys (one for each wrapping key used in encryption) or a reasonable maximum (such as 5). For details, see [Limit encrypted data keys \(p. 41\)](#).

The `--buffer` parameter returns plaintext only after all input is processed, including verifying the digital signature if one is present.

The `--decrypt-unsigned` parameter decrypts ciphertext and ensures that messages are unsigned before decryption. Use this parameter if you used the `--algorithm` parameter and selected an algorithm suite without digital signing to encrypt data. If the ciphertext is signed, decryption fails.

You can use `--decrypt` or `--decrypt-unsigned` for decryption but not both.

```
aws-encryption-cli --decrypt --input myEncryptedMessage \  
  --wrapping-keys key=1234abcd-12ab-34cd-56ef-1234567890ab \  
  --output myPlaintextData \  
  --metadata-output ~/metadata \  
  --max-encrypted-data-keys 1 \  
  --buffer \  
  --encryption-context purpose=test \  
  --commitment-policy require-encrypt-require-decrypt
```

The AWS Encryption CLI uses the wrapping key to decrypt the data key in the encrypted message. Then it uses the data key to decrypt your data. It returns your plaintext data and metadata about the operation.

How to specify wrapping keys

When you encrypt data in the AWS Encryption CLI, you need to specify at least one [wrapping key \(p. 7\)](#) (or *master key*). You can use AWS KMS keys in AWS Key Management Service (AWS KMS), wrapping keys from a custom [master key provider \(p. 7\)](#), or both. The custom master key provider can be any compatible Python master key provider.

To specify wrapping keys in versions 1.8.x and later, use the `--wrapping-keys` parameter (`-w`). The value of this parameter is a collection of [attributes \(p. 117\)](#) with the `attribute=value` format. The attributes that you use depend on the master key provider and the command.

- **AWS KMS.** In encrypt commands, you must specify a `--wrapping-keys` parameter with a **key** attribute. Beginning in version 2.1.x, the `--wrapping-keys` parameter is also required in decrypt commands. When decrypting, the `--wrapping-keys` parameter must have a **key** attribute or a **discovery** attribute with a value of `true` (but not both). Other attributes are optional.
- **Custom master key provider.** You must specify a `--wrapping-keys` parameter in every command. The parameter value must have **key** and **provider** attributes.

You can include [multiple `--wrapping-keys` parameters \(p. 119\)](#) and multiple **key** attributes in the same command.

Wrapping key parameter attributes

The value of the `--wrapping-keys` parameter consists of the following attributes and their values. A `--wrapping-keys` parameter (or `--master-keys` parameter) is required in all encrypt commands. Beginning in version 2.1.x, the `--wrapping-keys` parameter is also required when decrypting.

If an attribute name or value includes spaces or special characters, enclose both the name and value in quotation marks. For example, `--wrapping-keys key=12345 "provider=my cool provider"`.

Key: Specify a wrapping key

Use the **key** attribute to identify a wrapping key. When encrypting, the value can be any key identifier that the master key provider recognizes.

```
--wrapping-keys key=1234abcd-12ab-34cd-56ef-1234567890ab
```

In an encrypt command, you must include at least one **key** attribute and value. To encrypt your data key under multiple wrapping keys, use [multiple key attributes \(p. 119\)](#).

```
aws-encryption-cli --encrypt --wrapping-keys key=1234abcd-12ab-34cd-56ef-1234567890ab  
key=1a2b3c4d-5e6f-1a2b-3c4d-5e6f1a2b3c4d
```

In encrypt commands that use AWS KMS keys, the value of **key** can be the key ID, its key ARN, an alias name, or alias ARN. For example, this encrypt command uses an alias ARN in the value of the **key** attribute. For details about the key identifiers for an AWS KMS key, see [Key Identifiers](#) in the *AWS Key Management Service Developer Guide*.

```
aws-encryption-cli --encrypt --wrapping-keys key=arn:aws:kms:us-  
west-2:111122223333:alias/ExampleAlias
```

In decrypt commands that use a custom master key provider, **key** and **provider** attributes are required.

```
\\ Custom master key provider  
aws-encryption-cli --decrypt --wrapping-keys provider='myProvider' key='100101'
```

In decrypt commands that use AWS KMS, you can use the **key** attribute to specify the AWS KMS keys to use for decrypting, or the **discovery** attribute (p. 118) with a value of `true`, which lets the AWS Encryption CLI use any AWS KMS key that was used to encrypt the message. If you specify an AWS KMS key, it must be one of the wrapping keys used to encrypt the message.

Specifying the wrapping key is an [AWS Encryption SDK best practice](#) (p. 17). It assures that you use the AWS KMS key you intend to use.

In a decrypt command, the value of the **key** attribute must be a [key ARN](#).

```
\\ AWS KMS key  
aws-encryption-cli --decrypt --wrapping-keys key=arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab
```

Discovery: Use any AWS KMS key when decrypting

If you don't need to limit the AWS KMS keys to use when decrypting, you can use the **discovery** attribute with a value of `true`. A value of `true` allows the AWS Encryption CLI to decrypt using any AWS KMS key that encrypted the message. If you don't specify a **discovery** attribute, `discovery` is `false` (default). The **discovery** attribute is valid only in decrypt commands and only when the message was encrypted with AWS KMS keys.

The **discovery** attribute with a value of `true` is an alternative to using the **key** attribute to specify AWS KMS keys. When decrypting a message encrypted with AWS KMS keys, each `--wrapping-keys` parameter must have a **key** attribute or a **discovery** attribute with a value of `true`, but not both.

When `discovery` is `true`, it's a best practice to use the **discovery-partition** and **discovery-account** attributes to limit the AWS KMS keys used to those in the AWS accounts you specify. In the following example, the **discovery** attributes allow the AWS Encryption CLI to use any AWS KMS key in the specified AWS accounts.

```
aws-encryption-cli --decrypt --wrapping-keys \  
  discovery=true \  
  discovery-partition=aws \  
  discovery-account=111122223333 \  
  discovery-account=444455556666
```

Provider: Specify the master key provider

The **provider** attribute identifies the [master key provider](#) (p. 7). The default value is `aws-kms`, which represents AWS KMS. If you are using a different master key provider, the **provider** attribute is required.

```
--wrapping-keys key=12345 provider=my_custom_provider
```

For more information about using custom (non-AWS KMS) master key providers, see the **Advanced Configuration** topic in the [README](#) file for the [AWS Encryption CLI](#) repository.

Region: Specify an AWS Region

Use the **region** attribute to specify the AWS Region of an AWS KMS key. This attribute is valid only in encrypt commands and only when the master key provider is AWS KMS.

```
--encrypt --wrapping-keys key=alias/primary-key region=us-east-2
```

AWS Encryption CLI commands use the AWS Region that is specified in the **key** attribute value if it includes a region, such as an ARN. If the **key** value specifies a AWS Region, the **region** attribute is ignored.

The **region** attribute takes precedence over other region specifications. If you don't use a region attribute, AWS Encryption CLI commands uses the AWS Region specified in your AWS CLI [named profile](#), if any, or your default profile.

Profile: Specify a named profile

Use the **profile** attribute to specify an AWS CLI [named profile](#). Named profiles can include credentials and an AWS Region. This attribute is valid only when the master key provider is AWS KMS.

```
--wrapping-keys key=alias/primary-key profile=admin-1
```

You can use the **profile** attribute to specify alternate credentials in encrypt and decrypt commands. In an encrypt command, the AWS Encryption CLI uses the AWS Region in the named profile only when the **key** value does not include a region and there is no **region** attribute. In a decrypt command, the AWS Region in the name profile is ignored.

How to specify multiple wrapping keys

You can specify multiple wrapping keys (or *master keys*) in each command.

If you specify more than one wrapping key, the first wrapping key generates and encrypts the data key that is used to encrypt your data. The other wrapping keys encrypt the same data key. The resulting [encrypted message](#) (p. 8) contains the encrypted data ("ciphertext") and a collection of encrypted data keys, one encrypted by each wrapping key. Any of the wrapping can decrypt one encrypted data key and then decrypt the data.

There are two ways to specify multiple wrapping keys:

- Include multiple **key** attributes in the `--wrapping-keys` parameter value.

```
$key_oregon=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab
$key_ohio=arn:aws:kms:us-east-2:111122223333:key/0987ab65-43cd-21ef-09ab-87654321cdef

--wrapping-keys key=$key_oregon key=$key_ohio
```

- Include multiple `--wrapping-keys` parameters in the same command. Use this syntax when the attribute values that you specify do not apply to all of the wrapping keys in the command.

```
--wrapping-keys region=us-east-2 key=alias/test_key \  
--wrapping-keys region=us-west-1 key=alias/test_key
```

The **discovery** attribute with a value of `true` lets the AWS Encryption CLI use any AWS KMS key that encrypted the message. If you use multiple `--wrapping-keys` parameters in the same command, using `discovery=true` in any `--wrapping-keys` parameter effectively overrides the limits of the **key** attribute in other `--wrapping-keys` parameters.

For example, in the following command, the **key** attribute in the first `--wrapping-keys` parameter limits the AWS Encryption CLI to the specified AWS KMS key. However, the **discovery** attribute in the second `--wrapping-keys` parameter lets the AWS Encryption CLI use any AWS KMS key in the specified accounts to decrypt the message.

```
aws-encryption-cli --decrypt \  
  --wrapping-keys key=arn:aws:kms:us-  
west-2:11112223333:key/1234abcd-12ab-34cd-56ef-1234567890ab \  
  --wrapping-keys discovery=true \  
                    discovery-partition=aws \  
                    discovery-account=11112223333 \  
                    discovery-account=444455556666
```

How to provide input

The encrypt operation in the AWS Encryption CLI takes plaintext data as input and returns an [encrypted message](#) (p. 8). The decrypt operation takes an encrypted message as input and returns plaintext data.

The `--input` parameter (`-i`), which tells the AWS Encryption CLI where to find the input, is required in all AWS Encryption CLI commands.

You can provide input in any of the following ways:

- Use a file.

```
--input myData.txt
```

- Use a file name pattern.

```
--input testdir/*.xml
```

- Use a directory or directory name pattern. When the input is a directory, the `--recursive` parameter (`-r`, `-R`) is required.

```
--input testdir --recursive
```

- Pipe input to the command (stdin). Use a value of `-` for the `--input` parameter. (The `--input` parameter is always required.)

```
echo 'Hello World' | aws-encryption-cli --encrypt --input -
```

How to specify the output location

The `--output` parameter tells the AWS Encryption CLI where to write the results of the encryption or decryption operation. It is required in every AWS Encryption CLI command. The AWS Encryption CLI creates a new output file for every input file in the operation.

If an output file already exists, by default, the AWS Encryption CLI prints a warning, then overwrites the file. To prevent overwriting, use the `--interactive` parameter, which prompts you for confirmation before overwriting, or `--no-overwrite`, which skips the input if the output would cause an overwrite. To suppress the overwrite warning, use `--quiet`. To capture errors and warnings from the AWS Encryption CLI, use the `2>&1` redirection operator to write them to the output stream.

Note

Commands that overwrite output files begin by deleting the output file. If the command fails, the output file might already be deleted.

You can the output location in several ways.

- Specify a file name. If you specify a path to the file, all directories in the path must exist before the command runs.

```
--output myEncryptedData.txt
```

- Specify a directory. The output directory must exist before the command runs.

If the input contains subdirectories, the command reproduces the subdirectories under the specified directory.

```
--output Test
```

When the output location is a directory (without file names), the AWS Encryption CLI creates output file names based on the input file names plus a suffix. Encrypt operations append `.encrypted` to the input file name and the decrypt operations append `.decrypted`. To change the suffix, use the `--suffix` parameter.

For example, if you encrypt `file.txt`, the encrypt command creates `file.txt.encrypted`. If you decrypt `file.txt.encrypted`, the decrypt command creates `file.txt.encrypted.decrypted`.

- Write to the command line (stdout). Enter a value of `-` for the `--output` parameter. You can use `--output -` to pipe output to another command or program.

```
--output -
```

How to use an encryption context

The AWS Encryption CLI lets you provide an encryption context in encrypt and decrypt commands. It is not required, but it is a cryptographic best practice that we recommend.

An *encryption context* is a type of arbitrary, non-secret *additional authenticated data*. In the AWS Encryption CLI, the encryption context consists of a collection of `name=value` pairs. You can use any content in the pairs, including information about the files, data that helps you to find the encryption operation in logs, or data that your grants or policies require.

In an encrypt command

The encryption context that you specify in an encrypt command, along with any additional pairs that the [CMM \(p. 9\)](#) adds, is cryptographically bound to the encrypted data. It is also included (in plaintext) in the [encrypted message \(p. 8\)](#) that the command returns. If you are using an AWS KMS key, the encryption context also might appear in plaintext in audit records and logs, such as AWS CloudTrail.

The following example shows an encryption context with three name=value pairs.

```
--encryption-context purpose=test dept=IT class=confidential
```

In a decrypt command

In a decrypt command, the encryption context helps you to confirm that you are decrypting the right encrypted message.

You are not required to provide an encryption context in a decrypt command, even if an encryption context was used on encrypt. However, if you do, the AWS Encryption CLI verifies that every element in the encryption context of the decrypt command matches an element in the encryption context of the encrypted message. If any element does not match, the decrypt command fails.

For example, the following command decrypts the encrypted message only if its encryption context includes dept=IT.

```
aws-encryption-cli --decrypt --encryption-context dept=IT ...
```

An encryption context is an important part of your security strategy. However, when choosing an encryption context, remember that its values are not secret. Do not include any confidential data in the encryption context.

To specify an encryption context

- In an **encrypt** command, use the `--encryption-context` parameter with one or more name=value pairs. Use a space to separate each pair.

```
--encryption-context name=value [name=value] ...
```

- In a **decrypt** command, the `--encryption-context` parameter value can include name=value pairs, name elements (with no values), or a combination of both.

```
--encryption-context name[=value] [name] [name=value] ...
```

If the name or value in a name=value pair includes spaces or special characters, enclose the entire pair in quotation marks.

```
--encryption-context "department=software engineering" "AWS Region=us-west-2"
```

For example, this encrypt command includes an encryption context with two pairs, purpose=test and dept=23.

```
aws-encryption-cli --encrypt --encryption-context purpose=test dept=23 ...
```

These decrypt command would succeed. The encryption context in each commands is a subset of the original encryption context.

```
\\ Any one or both of the encryption context pairs  
aws-encryption-cli --decrypt --encryption-context dept=23 ...
```

```
\\ Any one or both of the encryption context names
aws-encryption-cli --decrypt --encryption-context purpose ...

\\ Any combination of names and pairs
aws-encryption-cli --decrypt --encryption-context dept purpose=test ...
```

However, these decrypt commands would fail. The encryption context in the encrypted message does not contain the specified elements.

```
aws-encryption-cli --decrypt --encryption-context dept=Finance ...
aws-encryption-cli --decrypt --encryption-context scope ...
```

How to specify a commitment policy

To set the [commitment policy](#) (p. 11) for the command, use the `--commitment-policy` [parameter](#) (p. 146). This parameter is introduced in version 1.8.x. It is valid in encrypt and decrypt commands. The commitment policy you set is valid only for the command in which it appears. If you do not set a commitment policy for a command, the AWS Encryption CLI uses the default value.

For example, the following parameter value sets the commitment policy to `require-encrypt-allow-decrypt`, which always encrypts with key commitment, but will decrypt a ciphertext that was encrypted with or without key commitment.

```
--commitment-policy require-encrypt-allow-decrypt
```

How to store parameters in a configuration file

You can save time and avoid typing errors by saving frequently used AWS Encryption CLI parameters and values in configuration files.

A *configuration file* is a text file that contains parameters and values for an AWS Encryption CLI command. When you refer to a configuration file in a AWS Encryption CLI command, the reference is replaced by the parameters and values in the configuration file. The effect is the same as if you typed the file content at the command line. A configuration file can have any name and it can be located in any directory that the current user can access.

The following example configuration file, `key.conf`, specifies two AWS KMS keys in different Regions.

```
--wrapping-keys key=arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab
--wrapping-keys key=arn:aws:kms:us-
east-2:111122223333:key/0987ab65-43cd-21ef-09ab-87654321cdef
```

To use the configuration file in a command, prefix the file name with an at sign (`@`). In a PowerShell console, use a backtick character to escape the at sign (``@`).

This example command uses the `key.conf` file in an encrypt command.

Bash

```
$ aws-encryption-cli -e @key.conf -i hello.txt -o testdir
```

PowerShell

```
PS C:\> aws-encryption-cli -e `@key.conf -i .\Hello.txt -o .\TestDir
```

Configuration file rules

The rules for using configuration files are as follows:

- You can include multiple parameters in each configuration file and list them in any order. List each parameter with its values (if any) on a separate line.
- Use # to add a comment to all or part of a line.
- You can include references to other configuration files. Do not use a backtick to escape the @ sign, even in PowerShell.
- If you use quotes in a configuration file, the quoted text cannot span multiple lines.

For example, this is the contents of an example `encrypt.conf` file.

```
# Archive Files
--encrypt
--output /archive/logs
--recursive
--interactive
--encryption-context class=unclassified dept=IT
--suffix # No suffix
--metadata-output ~/metadata
@caching.conf # Use limited caching
```

You can also include multiple configuration files in a command. This example command uses both the `encrypt.conf` and `master-keys.conf` configurations files.

Bash

```
$ aws-encryption-cli -i /usr/logs @encrypt.conf @master-keys.conf
```

PowerShell

```
PS C:\> aws-encryption-cli -i $home\Test\*.log `@encrypt.conf `@master-keys.conf
```

Next: [Try the AWS Encryption CLI examples \(p. 124\)](#)

Examples of the AWS Encryption CLI

Use the following examples to try the AWS Encryption CLI on the platform you prefer. For help with master keys and other parameters, see [How to use the AWS Encryption CLI \(p. 115\)](#). For a quick reference, see [AWS Encryption SDK CLI syntax and parameter reference \(p. 140\)](#).

Note

The following examples use the syntax for AWS Encryption CLI version 2.1.x. New security features were originally released in AWS Encryption CLI versions 1.7.x and 2.0.x. However, AWS Encryption CLI version 1.8.x replaces version 1.7.x and AWS Encryption CLI 2.1.x replaces 2.0.x. For details, see the relevant [security advisory](#) in the [aws-encryption-sdk-cli](#) repository on GitHub.

For an example showing how to use the security feature that limits encrypted data keys, see [Limit encrypted data keys \(p. 41\)](#).

For an example showing how to use AWS KMS multi-Region keys, see [Use multi-Region AWS KMS keys \(p. 21\)](#).

- [Using data key caching \(p. 138\)](#)

Encrypting a file

This example uses the AWS Encryption CLI to encrypt the contents of the `hello.txt` file, which contains a "Hello World" string.

When you run an `encrypt` command on a file, the AWS Encryption CLI gets the contents of the file, generates a unique [data key \(p. 6\)](#), encrypts the file contents under the data key, and then writes the [encrypted message \(p. 8\)](#) to a new file.

The first command saves the key ARN of an AWS KMS key in the `$keyArn` variable. When encrypting with an AWS KMS key, you can identify it by using a key ID, key ARN, alias name, or alias ARN. For details about the key identifiers for an AWS KMS key, see [Key Identifiers](#) in the *AWS Key Management Service Developer Guide*.

The second command encrypts the file contents. The command uses the `--encrypt` parameter to specify the operation and the `--input` parameter to indicate the file to encrypt. The [--wrapping-keys parameter \(p. 117\)](#), and its required `key` attribute, tell the command to use the AWS KMS key represented by the key ARN.

The command uses the `--metadata-output` parameter to specify a text file for the metadata about the encryption operation. As a best practice, the command uses the `--encryption-context` parameter to specify an [encryption context \(p. 121\)](#).

This command also uses the [--commitment-policy parameter \(p. 146\)](#) to set the commitment policy explicitly. In version 1.8.x, this parameter is required when you use the `--wrapping-keys` parameter. Beginning in version 2.1.x, the `--commitment-policy` parameter is optional, but recommended.

The value of the `--output` parameter, a dot (`.`), tells the command to write the output file to the current directory.

Bash

```
\\ To run this example, replace the fictitious key ARN with a valid value.
$ keyArn=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab

$ aws-encryption-cli --encrypt \
  --input hello.txt \
  --wrapping-keys key=$keyArn \
  --metadata-output ~/metadata \
  --encryption-context purpose=test \
  --commitment-policy require-encrypt-require-decrypt \
  --output .
```

PowerShell

```
# To run this example, replace the fictitious key ARN with a valid value.
```

```
PS C:\> $keyArn = 'arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'  
  
PS C:\> aws-encryption-cli --encrypt `  
    --input Hello.txt `   
    --wrapping-keys key=$keyArn `   
    --metadata-output $home\Metadata.txt `   
    --commitment-policy require-encrypt-require-decrypt `   
    --encryption-context purpose=test `   
    --output .
```

When the encrypt command succeeds, it does not return any output. To determine whether the command succeeded, check the Boolean value in the \$? variable. When the command succeeds, the value of \$? is 0 (Bash) or True (PowerShell). When the command fails, the value of \$? is non-zero (Bash) or False (PowerShell).

Bash

```
$ echo $?  
0
```

PowerShell

```
PS C:\> $?  
True
```

You can also use a directory listing command to see that the encrypt command created a new file, `hello.txt.encrypted`. Because the encrypt command did not specify a file name for the output, the AWS Encryption CLI wrote the output to a file with the same name as the input file plus a `.encrypted` suffix. To use a different suffix, or suppress the suffix, use the `--suffix` parameter.

The `hello.txt.encrypted` file contains an [encrypted message \(p. 8\)](#) that includes the ciphertext of the `hello.txt` file, an encrypted copy of the data key, and additional metadata, including the encryption context.

Bash

```
$ ls  
hello.txt  hello.txt.encrypted
```

PowerShell

```
PS C:\> dir  
  
    Directory: C:\TestCLI  
  
Mode                LastWriteTime         Length Name  
----                -  
-a----            9/15/2017   5:57 PM             11 Hello.txt  
-a----            9/17/2017   1:06 PM          585 Hello.txt.encrypted
```

Decrypting a file

This example uses the AWS Encryption CLI to decrypt the contents of the `Hello.txt.encrypted` file that was encrypted in the previous example.

The `decrypt` command uses the `--decrypt` parameter to indicate the operation and `--input` parameter to identify the file to decrypt. The value of the `--output` parameter is a dot that represents the current directory.

The `--wrapping-keys` parameter with a **key** attribute specifies the wrapping key used to decrypt the encrypted message. In `decrypt` commands with AWS KMS keys, the value of the key attribute must be a [key ARN](#). The `--wrapping-keys` parameter is required in a `decrypt` command. If you are using AWS KMS keys, you can use the **key** attribute to specify AWS KMS keys for decrypting or the **discovery** attribute with a value of `true` (but not both). If you are using a custom master key provider, the **key** and **provider** attributes are required.

The `--commitment-policy` parameter ([p. 146](#)) is optional beginning in version 2.1.x, but it is recommended. Using it explicitly makes your intent clear, even if you specify the default value, `require-encrypt-require-decrypt`.

The `--encryption-context` parameter is optional in the `decrypt` command, even when an [encryption context](#) ([p. 121](#)) is provided in the `encrypt` command. In this case, the `decrypt` command uses the same encryption context that was provided in the `encrypt` command. Before decrypting, the AWS Encryption CLI verifies that the encryption context in the encrypted message includes a `purpose=test` pair. If it does not, the `decrypt` command fails.

The `--metadata-output` parameter specifies a file for metadata about the decryption operation. The value of the `--output` parameter, a dot (`.`), writes the output file to the current directory.

As a best practice, use the `--max-encrypted-data-keys` parameter to avoid decrypting a malformed message with an excessive number of encrypted data keys. Specify the expected number of encrypted data keys (one for each wrapping key used in encryption) or a reasonable maximum (such as 5). For details, see [Limit encrypted data keys](#) ([p. 41](#)).

The `--buffer` returns plaintext only after all input is processed, including verifying the digital signature if one is present.

Bash

```
\\ To run this example, replace the fictitious key ARN with a valid value.
$ keyArn=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab

$ aws-encryption-cli --decrypt \
    --input hello.txt.encrypted \
    --wrapping-keys key=$keyArn \
    --commitment-policy require-encrypt-require-decrypt \
    --encryption-context purpose=test \
    --metadata-output ~/metadata \
    --max-encrypted-data-keys 1 \
    --buffer \
    --output .
```

PowerShell

```
\\ To run this example, replace the fictitious key ARN with a valid value.
PS C:\> $keyArn = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

PS C:\> aws-encryption-cli --decrypt `
    --input Hello.txt.encrypted `
    --wrapping-keys key=$keyArn `
    --commitment-policy require-encrypt-require-decrypt `
    --encryption-context purpose=test `
    --metadata-output $home\Metadata.txt `
    --max-encrypted-data-keys 1 `
```

```
--buffer `
--output .
```

When a decrypt command succeeds, it does not return any output. To determine whether the command succeeded, get the value of the `$?` variable. You can also use a directory listing command to see that the command created a new file with a `.decrypted` suffix. To see the plaintext content, use a command to get the file content, such as `cat` or [Get-Content](#).

Bash

```
$ ls
hello.txt  hello.txt.encrypted  hello.txt.encrypted.decrypted

$ cat hello.txt.encrypted.decrypted
Hello World
```

PowerShell

```
PS C:\> dir

Directory: C:\TestCLI

Mode                LastWriteTime         Length Name
----                -
-a----           9/17/2017   1:01 PM             11 Hello.txt
-a----           9/17/2017   1:06 PM          585 Hello.txt.encrypted
-a----           9/17/2017   1:08 PM             11 Hello.txt.encrypted.decrypted

PS C:\> Get-Content Hello.txt.encrypted.decrypted
Hello World
```

Encrypting all files in a directory

This example uses the AWS Encryption CLI to encrypt the contents of all of the files in a directory.

When a command affects multiple files, the AWS Encryption CLI processes each file individually. It gets the file contents, gets a unique [data key](#) (p. 6) for the file from the master key, encrypts the file contents under the data key, and writes the results to a new file in the output directory. As a result, you can decrypt the output files independently.

This listing of the `TestDir` directory shows the plaintext files that we want to encrypt.

Bash

```
$ ls testdir
cool-new-thing.py  hello.txt  employees.csv
```

PowerShell

```
PS C:\> dir C:\TestDir

Directory: C:\TestDir

Mode                LastWriteTime         Length Name
----                -
-a----           9/17/2017   1:01 PM             11 Hello.txt
-a----           9/17/2017   1:06 PM          585 Hello.txt.encrypted
-a----           9/17/2017   1:08 PM             11 Hello.txt.encrypted.decrypted
```

-a----	9/12/2017	3:11 PM	2139 cool-new-thing.py
-a----	9/15/2017	5:57 PM	11 Hello.txt
-a----	9/17/2017	1:44 PM	46 Employees.csv

The first command saves the [Amazon Resource Name \(ARN\)](#) of an AWS KMS key in the `$keyArn` variable.

The second command encrypts the content of files in the `TestDir` directory and writes the files of encrypted content to the `TestEnc` directory. If the `TestEnc` directory doesn't exist, the command fails. Because the input location is a directory, the `--recursive` parameter is required.

The `--wrapping-keys` parameter (p. 117), and its required `key` attribute, specify the wrapping key to use. The `encrypt` command includes an [encryption context](#) (p. 121), `dept=IT`. When you specify an encryption context in a command that encrypts multiple files, the same encryption context is used for all of the files.

The command also has a `--metadata-output` parameter to tell the AWS Encryption CLI where to write the metadata about the encryption operations. The AWS Encryption CLI writes one metadata record for each file that was encrypted.

The `--commitment-policy` parameter (p. 123) is optional beginning in version 2.1.x, but it is recommended. If the command or script fails because it cannot decrypt a ciphertext, the explicit commitment policy setting might help you to detect the problem quickly.

When the command completes, the AWS Encryption CLI writes the encrypted files to the `TestEnc` directory, but it does not return any output.

The final command lists the files in the `TestEnc` directory. There is one output file of encrypted content for each input file of plaintext content. Because the command did not specify an alternate suffix, the `encrypt` command appended `.encrypted` to each of the input file names.

Bash

```
# To run this example, replace the fictitious key ARN with a valid master key
identifier.
$ keyArn=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab

$ aws-encryption-cli --encrypt \
    --input testdir --recursive\
    --wrapping-keys key=$keyArn \
    --encryption-context dept=IT \
    --commitment-policy require-encrypt-require-decrypt \
    --metadata-output ~/metadata \
    --output testenc

$ ls testenc
cool-new-thing.py.encrypted  employees.csv.encrypted  hello.txt.encrypted
```

PowerShell

```
# To run this example, replace the fictitious key ARN with a valid master key
identifier.
PS C:\> $keyArn = arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab

PS C:\> aws-encryption-cli --encrypt `
    --input .\TestDir --recursive `
    --wrapping-keys key=$keyArn `
    --encryption-context dept=IT `
    --commitment-policy require-encrypt-require-decrypt `
```

```
--metadata-output .\Metadata\Metadata.txt `
--output .\TestEnc

PS C:\> dir .\TestEnc

    Directory: C:\TestEnc

Mode                LastWriteTime         Length Name
----                -
-a----            9/17/2017    2:32 PM          2713 cool-new-thing.py.encrypted
-a----            9/17/2017    2:32 PM           620 Hello.txt.encrypted
-a----            9/17/2017    2:32 PM           585 Employees.csv.encrypted
```

Decrypting all files in a directory

This example decrypts all files in a directory. It starts with the files in the `TestEnc` directory that were encrypted in the previous example.

Bash

```
$ ls testenc
cool-new-thing.py.encrypted  hello.txt.encrypted  employees.csv.encrypted
```

PowerShell

```
PS C:\> dir C:\TestEnc

    Directory: C:\TestEnc

Mode                LastWriteTime         Length Name
----                -
-a----            9/17/2017    2:32 PM          2713 cool-new-thing.py.encrypted
-a----            9/17/2017    2:32 PM           620 Hello.txt.encrypted
-a----            9/17/2017    2:32 PM           585 Employees.csv.encrypted
```

This `decrypt` command decrypts all of the files in the `TestEnc` directory and writes the plaintext files to the `TestDec` directory. The `--wrapping-keys` parameter with a **key** attribute and a [key ARN](#) value tells the AWS Encryption CLI which AWS KMS keys to use to decrypt the files. The command uses the `--interactive` parameter to tell the AWS Encryption CLI to prompt you before overwriting a file with the same name.

This command also uses the encryption context that was provided when the files were encrypted. When decrypting multiple files, the AWS Encryption CLI checks the encryption context of every file. If the encryption context check on any file fails, the AWS Encryption CLI rejects the file, writes a warning, records the failure in the metadata, and then continues checking the remaining files. If the AWS Encryption CLI fails to decrypt a file for any other reason, the entire `decrypt` command fails immediately.

In this example, the encrypted messages in all of the input files contain the `dept=IT` encryption context element. However, if you were decrypting messages with different encryption contexts, you might still be able to verify part of the encryption context. For example, if some messages had an encryption context of `dept=finance` and others had `dept=IT`, you could verify that the encryption context always contains a `dept` name without specifying the value. If you wanted to be more specific, you could decrypt the files in separate commands.

The `decrypt` command does not return any output, but you can use a directory listing command to see that it created new files with the `.decrypted` suffix. To see the plaintext content, use a command to get the file content.

Bash

```
# To run this example, replace the fictitious key ARN with a valid master key
# identifier.
$ keyArn=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab

$ aws-encryption-cli --decrypt \
  --input testenc --recursive \
  --wrapping-keys key=$keyArn \
  --encryption-context dept=IT \
  --commitment-policy require-encrypt-require-decrypt \
  --metadata-output ~/metadata \
  --max-encrypted-data-keys 1 \
  --buffer \
  --output testdec --interactive

$ ls testdec
cool-new-thing.py.encrypted.decrypted  hello.txt.encrypted.decrypted
employees.csv.encrypted.decrypted
```

PowerShell

```
# To run this example, replace the fictitious key ARN with a valid master key
# identifier.
PS C:\> $keyArn = 'arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

PS C:\> aws-encryption-cli --decrypt `
  --input C:\TestEnc --recursive `
  --wrapping-keys key=$keyArn `
  --encryption-context dept=IT `
  --commitment-policy require-encrypt-require-decrypt `
  --metadata-output $home\Metadata.txt `
  --max-encrypted-data-keys 1 `
  --buffer `
  --output C:\TestDec --interactive

PS C:\> dir .\TestDec

Mode                LastWriteTime         Length Name
----                -
-a----           10/8/2017   4:57 PM          2139 cool-new-thing.py.encrypted.decrypted
-a----           10/8/2017   4:57 PM           46 Employees.csv.encrypted.decrypted
-a----           10/8/2017   4:57 PM           11 Hello.txt.encrypted.decrypted
```

Encrypting and decrypting on the command line

These examples show you how to pipe input to commands (stdin) and write output to the command line (stdout). They explain how to represent stdin and stdout in a command and how to use the built-in Base64 encoding tools to prevent the shell from misinterpreting non-ASCII characters.

This example pipes a plaintext string to an encrypt command and saves the encrypted message in a variable. Then, it pipes the encrypted message in the variable to a decrypt command, which writes its output to the pipeline (stdout).

The example consists of three commands:

- The first command saves the [key ARN](#) of an AWS KMS key in the `$keyArn` variable.

Bash

```
$ keyArn=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab
```

PowerShell

```
PS C:\> $keyArn = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'
```

- The second command pipes the `Hello World` string to the `encrypt` command and saves the result in the `$encrypted` variable.

The `--input` and `--output` parameters are required in all AWS Encryption CLI commands. To indicate that input is being piped to the command (stdin), use a hyphen (-) for the value of the `--input` parameter. To send the output to the command line (stdout), use a hyphen for the value of the `--output` parameter.

The `--encode` parameter Base64-encodes the output before returning it. This prevents the shell from misinterpreting the non-ASCII characters in the encrypted message.

Because this command is just a proof of concept, we omit the encryption context and suppress the metadata (-s).

Bash

```
$ encrypted=$(echo 'Hello World' | aws-encryption-cli --encrypt -S \
--input - --output - --encode \
--wrapping-keys key=$keyArn )
```

PowerShell

```
PS C:\> $encrypted = 'Hello World' | aws-encryption-cli --encrypt -S `
--input - --output - --encode
`
--wrapping-keys key=$keyArn
```

- The third command pipes the encrypted message in the `$encrypted` variable to the `decrypt` command.

This `decrypt` command uses `--input -` to indicate that input is coming from the pipeline (stdin) and `--output -` to send the output to the pipeline (stdout). (The input parameter takes the location of the input, not the actual input bytes, so you cannot use the `$encrypted` variable as the value of the `--input` parameter.)

This example uses the **discovery** attribute of the `--wrapping-keys` parameter to allow the AWS Encryption CLI to use any AWS KMS key to decrypt the data. It doesn't specify a [commitment policy \(p. 11\)](#), so it uses the default value for version 2.1.x and later, `require-encrypt-require-decrypt`.

Because the output was encrypted and then encoded, the `decrypt` command uses the `--decode` parameter to decode Base64-encoded input before decrypting it. You can also use the `--decode` parameter to decode Base64-encoded input before encrypting it.

Again, the command omits the encryption context and suppresses the metadata (-s).

Bash

```
$ echo $encrypted | aws-encryption-cli --decrypt --wrapping-keys discovery=true --input - --output - --decode --buffer -S
Hello World
```

PowerShell

```
PS C:\> $encrypted | aws-encryption-cli --decrypt --wrapping-keys discovery=$true --input - --output - --decode --buffer -S
Hello World
```

You can also perform the encrypt and decrypt operations in a single command without the intervening variable.

As in the previous example, the `--input` and `--output` parameters have a `-` value and the command uses the `--encode` parameter to encode the output and the `--decode` parameter to decode the input.

Bash

```
$ keyArn=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab

$ echo 'Hello World' |
  aws-encryption-cli --encrypt --wrapping-keys key=$keyArn --input - --output -
--encode -S |
  aws-encryption-cli --decrypt --wrapping-keys discovery=true --input - --
output - --decode -S
Hello World
```

PowerShell

```
PS C:\> $keyArn = 'arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

PS C:\> 'Hello World' |
  aws-encryption-cli --encrypt --wrapping-keys key=$keyArn --input - --
output - --encode -S |
  aws-encryption-cli --decrypt --wrapping-keys discovery=$true --input -
--output - --decode -S
Hello World
```

Using multiple master keys

This example shows how to use multiple master keys when encrypting and decrypting data in the AWS Encryption CLI.

When you use multiple master keys to encrypt data, any one of the master keys can be used to decrypt the data. This strategy assures that you can decrypt the data even if one of the master keys is unavailable. If you are storing the encrypted data in multiple AWS Regions, this strategy lets you use a master key in the same Region to decrypt the data.

When you encrypt with multiple master keys, the first master key plays a special role. It generates the data key that is used to encrypt the data. The remaining master keys encrypt the plaintext data key. The resulting [encrypted message \(p. 8\)](#) includes the encrypted data and a collection of encrypted data keys, one for each master key. Although the first master key generated the data key, any of the master keys can decrypt one of the data keys, which can be used to decrypt the data.

Encrypting with three master keys

This example command uses three wrapping keys to encrypt the `Finance.log` file, one in each of three AWS Regions.

It writes the encrypted message to the `Archive` directory. The command uses the `--suffix` parameter with no value to suppress the suffix, so the input and output file names will be the same.

The command uses the `--wrapping-keys` parameter with three **key** attributes. You can also use multiple `--wrapping-keys` parameters in the same command.

To encrypt the log file, the AWS Encryption CLI asks the first wrapping key in the list, `$key1`, to generate the data key that it uses to encrypt the data. Then, it uses each of the other wrapping keys to encrypt a plaintext copy of the same data key. The encrypted message in the output file includes all three of the encrypted data keys.

Bash

```
$ key1=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab
$ key2=arn:aws:kms:us-east-2:111122223333:key/0987ab65-43cd-21ef-09ab-87654321cdef
$ key3=arn:aws:kms:ap-southeast-1:111122223333:key/1a2b3c4d-5e6f-1a2b-3c4d-5e6f1a2b3c4d

$ aws-encryption-cli --encrypt --input /logs/finance.log \
  --output /archive --suffix \
  --encryption-context class=log \
  --metadata-output ~/metadata \
  --wrapping-keys key=$key1 key=$key2 key=$key3
```

PowerShell

```
PS C:\> $key1 = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'
PS C:\> $key2 = 'arn:aws:kms:us-east-2:111122223333:key/0987ab65-43cd-21ef-09ab-87654321cdef'
PS C:\> $key3 = 'arn:aws:kms:ap-southeast-1:111122223333:key/1a2b3c4d-5e6f-1a2b-3c4d-5e6f1a2b3c4d'

PS C:\> aws-encryption-cli --encrypt --input D:\Logs\Finance.log `
  --output D:\Archive --suffix `
  --encryption-context class=log `
  --metadata-output $home\Metadata.txt `
  --wrapping-keys key=$key1 key=$key2 key=$key3
```

This command decrypts the encrypted copy of the `Finance.log` file and writes it to a `Finance.log.clear` file in the `Finance` directory. To decrypt data encrypted under three AWS KMS keys, you can specify the same three AWS KMS keys or any subset of them. This example specifies only one of the AWS KMS keys.

To tell the AWS Encryption CLI which AWS KMS keys to use to decrypt your data, use the **key** attribute of the `--wrapping-keys` parameter. When decrypting with AWS KMS keys, the value of the **key** attribute must be a [key ARN](#).

You must have permission to call the [Decrypt API](#) on the AWS KMS keys you specify. For more information, see [Authentication and Access Control for AWS KMS](#).

As a best practice, this examples use the `--max-encrypted-data-keys` parameter to avoid decrypting a malformed message with an excessive number of encrypted data keys. Even though this example uses only one wrapping key for decryption, the encrypted message has three (3) encrypted data keys; one for each of the three wrapping keys used when encrypting. Specify the expected number of encrypted

data keys or a reasonable maximum value, such as 5. If you specify a maximum value less than 3, the command fails. For details, see [Limit encrypted data keys \(p. 41\)](#).

Bash

```
$ aws-encryption-cli --decrypt --input /archive/finance.log \  
    --wrapping-keys key=$key1 \  
    --output /finance --suffix '.clear' \  
    --metadata-output ~/metadata \  
    --max-encrypted-data-keys 3 \  
    --buffer \  
    --encryption-context class=log
```

PowerShell

```
PS C:\> aws-encryption-cli --decrypt \  
    --input D:\Archive\Finance.log \  
    --wrapping-keys key=$key1 \  
    --output D:\Finance --suffix '.clear' \  
    --metadata-output .\Metadata\Metadata.txt \  
    --max-encrypted-data-keys 3 \  
    --buffer \  
    --encryption-context class=log
```

Encrypting and decrypting in scripts

This example shows how to use the AWS Encryption CLI in scripts. You can write scripts that just encrypt and decrypt data, or scripts that encrypt or decrypt as part of a data management process.

In this example, the script gets a collection of log files, compresses them, encrypts them, and then copies the encrypted files to an Amazon S3 bucket. This script processes each file separately, so that you can decrypt and expand them independently.

When you compress and encrypt files, be sure to compress before you encrypt. Properly encrypted data is not compressible.

Warning

Be careful when compressing data that includes both secrets and data that might be controlled by a malicious actor. The final size of the compressed data might inadvertently reveal sensitive information about its contents.

Bash

```
# Continue running even if an operation fails.  
set +e  
  
dir=$1  
encryptionContext=$2  
s3bucket=$3  
s3folder=$4  
masterKeyProvider="aws-kms"  
metadataOutput="/tmp/metadata-$(date +%s)"  
  
compress(){  
    gzip -qf $1  
}  
  
encrypt(){  
    # -e encrypt
```

```
# -i input
# -o output
# --metadata-output unique file for metadata
# -m masterKey read from environment variable
# -c encryption context read from the second argument.
# -v be verbose
aws-encryption-cli -e -i ${1} -o $(dirname ${1}) --metadata-output
${metadataOutput} -m key="${masterKey}" provider="${masterKeyProvider}" -c
"${encryptionContext}" -v
}

s3put (){
    # copy file argument 1 to s3 location passed into the script.
    aws s3 cp ${1} ${s3bucket}/${s3folder}
}

# Validate all required arguments are present.
if [ "${dir}" ] && [ "${encryptionContext}" ] && [ "${s3bucket}" ] && [ "${s3folder}" ]
&& [ "${masterKey}" ]; then

# Is $dir a valid directory?
test -d "${dir}"
if [ $? -ne 0 ]; then
    echo "Input is not a directory; exiting"
    exit 1
fi

# Iterate over all the files in the directory, except *gz and *encrypted (in case of a
re-run).
for f in $(find ${dir} -type f \( -name "*" ! -name \*.gz ! -name \*encrypted \) ); do
    echo "Working on $f"
    compress ${f}
    encrypt ${f}.gz
    rm -f ${f}.gz
    s3put ${f}.gz.encrypted
done;
else
    echo "Arguments: <Directory> <encryption context> <s3://bucketname> <s3 folder>"
    echo " and ENV var \${masterKey} must be set"
    exit 255
fi
```

                    -c $EncryptionContext `
                    --metadata-output $MetadataDirectory `
                    -v) 2>&1

                # Check error status
                if ($? -eq $false)

```

By default, the AWS Encryption CLI (and other versions of the AWS Encryption SDK) generates a unique data key for each file that it encrypts. Although using a unique data key for each operation is a cryptographic best practice, limited reuse of data keys is acceptable for some situations. If you are considering data key caching, consult with a security engineer to understand the security requirements of your application and determine security thresholds that are right for you.

The command in this example encrypts a large directory with multiple subdirectories that contain a total of approximately 800 small log files. The first command saves the ARN of the AWS KMS key in a `keyARN` variable. The second command encrypts all of the files in the input directory (recursively) and writes them to an archive directory. The command uses the `--suffix` parameter to specify the `.archive` suffix.

The optional **max_messages_encrypted** attribute is set to 10 messages, so a single data key is never used to encrypt more than 10 files. Limiting the number of files encrypted by each data key reduces the number of files that would be affected in the unlikely event that a data key was compromised.

Bash

```
$ aws-encryption-cli --encrypt \
  --input /var/log/httpd --recursive \
  --output ~/archive --suffix .archive \
  --wrapping-keys key=$keyArn \
  --encryption-context class=log \
  --suppress-metadata \
  --caching capacity=1 max_age=10 max_messages_encrypted=10
```

PowerShell

```
PS C:\> $keyARN = 'arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

PS C:\> aws-encryption-cli --encrypt `
  --input C:\Windows\Logs --recursive `
  --output $home\Archive --suffix '.archive' `
  --wrapping-keys key=$keyARN `
  --encryption-context class=log `
  --suppress-metadata `
  --caching capacity=1 max_age=10 max_messages_encrypted=10
```

To test the effect of data key caching, this example uses the [Measure-Command](#) cmdlet in PowerShell. When you run this example without data key caching, it takes about 25 seconds to complete. This process generates a new data key for each file in the directory.

```
PS C:\> Measure-Command {aws-encryption-cli --encrypt `
  --input C:\Windows\Logs --recursive `
  --output $home\Archive --suffix '.archive' `
  --wrapping-keys key=$keyARN `
  --encryption-context class=log `
  --suppress-metadata }

Days           : 0
Hours          : 0
Minutes        : 0
Seconds        : 25
Milliseconds    : 453
Ticks          : 254531202
TotalDays      : 0.000294596298611111
TotalHours     : 0.007070311166666667
TotalMinutes   : 0.42421867
TotalSeconds   : 25.4531202
TotalMilliseconds : 25453.1202
```

Data key caching makes the process quicker, even when you limit each data key to a maximum of 10 files. The command now takes less than 12 seconds to complete and reduces the number of calls to the master key provider to 1/10 of the original value.

```
PS C:\> Measure-Command {aws-encryption-cli --encrypt `
  --input C:\Windows\Logs --recursive `
  --output $home\Archive --suffix '.archive' `
  --wrapping-keys key=$keyARN `
  --encryption-context class=log `
  --suppress-metadata `
  --caching capacity=1 max_age=10
  max_messages_encrypted=10}

Days           : 0
Hours          : 0
```

```
Minutes      : 0
Seconds      : 11
Milliseconds : 813
Ticks        : 118132640
TotalDays    : 0.000136727592592593
TotalHours   : 0.003281462222222222
TotalMinutes : 0.1968877333333333
TotalSeconds : 11.813264
TotalMilliseconds : 11813.264
```

If you eliminate the `max_messages_encrypted` restriction, all files are encrypted under the same data key. This change increases the risk of reusing data keys without making the process much faster. However, it reduces the number of calls to the master key provider to 1.

```
PS C:\> Measure-Command {aws-encryption-cli --encrypt `
                                           --input C:\Windows\Logs --recursive `
                                           --output $home\Archive --suffix '.archive' `
                                           --wrapping-keys key=$keyARN `
                                           --encryption-context class=log `
                                           --suppress-metadata `
                                           --caching capacity=1 max_age=10}

AWS Encryption SDK CLI syntax and parameter reference

This topic provides syntax diagrams and brief parameter descriptions to help you use the AWS Encryption SDK Command Line Interface (CLI). For help with wrapping keys and other parameters, see [How to use the AWS Encryption CLI \(p. 115\)](#). For examples, see [Examples of the AWS Encryption CLI \(p. 124\)](#). For complete documentation, see [Read the Docs](#).

Topics

- [AWS Encryption CLI syntax \(p. 140\)](#)
- [AWS Encryption CLI command line parameters \(p. 142\)](#)
- [Advanced parameters \(p. 148\)](#)

AWS Encryption CLI syntax

These AWS Encryption CLI syntax diagrams show the syntax for each task that you perform with the AWS Encryption CLI. They represent recommended syntax in AWS Encryption CLI version 2.1.x and later.

New security features were originally released in AWS Encryption CLI versions 1.7.x and 2.0.x. However, AWS Encryption CLI version 1.8.x replaces version 1.7.x and AWS Encryption CLI 2.1.x replaces 2.0.x. For details, see the relevant [security advisory](#) in the [aws-encryption-sdk-cli](#) repository on GitHub.

Note

Unless noted in the parameter description, each parameter or attribute can be used only once in each command.

If you use an attribute that a parameter does not support, the AWS Encryption CLI ignores that unsupported attribute without a warning or error.

Get help

To get the full AWS Encryption CLI syntax with parameter descriptions, use `--help` or `-h`.

```
aws-encryption-cli (--help | -h)
```

Get the version

To get the version number of your AWS Encryption CLI installation, use `--version`. Be sure to include the version when you ask questions, report problems, or share tips about using the AWS Encryption CLI.

```
aws-encryption-cli --version
```

Encrypt data

The following syntax diagram shows the parameters that an **encrypt** command uses.

```
aws-encryption-cli --encrypt
    --input <input> [--recursive] [--decode]
    --output <output> [--interactive] [--no-overwrite] [--suffix
    [<suffix>]] [--encode]
    --wrapping-keys [--wrapping-keys] ...
        key=<keyID> [key=<keyID>] ...
        [provider=<provider-name>] [region=<aws-region>] [profile=<aws-
profile>]
    --metadata-output <location> [--overwrite-metadata] | --suppress-
metadata]
    [--commitment-policy <commitment-policy>]
    [--encryption-context <encryption-context> [<encryption-context>
...]]
    [--max-encrypted-data-keys <integer>]
    [--algorithm <algorithm_suite>]
    [--caching <attributes>]
    [--frame-length <length>]
    [-v | -vv | -vvv | -vvvv]
    [--quiet]
```

Decrypt data

The following syntax diagram shows the parameters that a **decrypt** command uses.

In version 1.8.x, the `--wrapping-keys` parameter is optional when decrypting, but recommended. Beginning in version 2.1.x, the `--wrapping-keys` parameter is required when encrypting and decrypting. For AWS KMS keys, you can use the **key** attribute to specify wrapping keys (best practice) or set the **discovery** attribute to `true`, which doesn't limit the wrapping keys that the AWS Encryption CLI can use.

```
aws-encryption-cli --decrypt (or [--decrypt-unsigned])
    --input <input> [--recursive] [--decode]
    --output <output> [--interactive] [--no-overwrite] [--suffix
    [<suffix>]] [--encode]
    --wrapping-keys [--wrapping-keys] ...
```

```
[key=<keyID>] [key=<keyID>] ...
[discovery={true|false}] [discovery-partition=<aws-partition-
name>] discovery-account=<aws-account-ID> [discovery-account=<aws-account-ID>] ...]
[provider=<provider-name>] [region=<aws-region>] [profile=<aws-
profile>]
--metadata-output <location> [--overwrite-metadata] | --suppress-
metadata]
[--commitment-policy <commitment-policy>]
[--encryption-context <encryption_context> [<encryption_context>
...]]
[--buffer]
[--max-encrypted-data-keys <integer>]
[--caching <attributes>]
[--max-length <length>]
[-v | -vv | -vvv | -vvvv]
[--quiet]
```

Use configuration files

You can refer to configuration files that contain parameters and their values. This is equivalent to typing the parameters and values in the command. For an example, see [How to store parameters in a configuration file \(p. 123\)](#).

```
aws-encryption-cli @<configuration_file>

# In a PowerShell console, use a backtick to escape the @.
aws-encryption-cli `@<configuration_file>
```

AWS Encryption CLI command line parameters

This list provides a basic description of the AWS Encryption CLI command parameters. For a complete description, see the [aws-encryption-sdk-cli documentation](#).

--encrypt (-e)

Encrypts the input data. Every command must have an --encrypt, or --decrypt, or --decrypt-unsigned parameter.

--decrypt (-d)

Decrypts the input data. Every command must have an --encrypt, --decrypt, or --decrypt-unsigned parameter.

--decrypt-unsigned [Introduced in versions 1.9.x and 2.2.x]

The --decrypt-unsigned parameter decrypts ciphertext and ensures that messages are unsigned before decryption. Use this parameter if you used the --algorithm parameter and selected an algorithm suite without digital signing to encrypt data. If the ciphertext is signed, decryption fails.

You can use --decrypt or --decrypt-unsigned for decryption but not both.

--wrapping-keys (-w) [Introduced in version 1.8.x]

Specifies the [wrapping keys \(p. 7\)](#) (or *master keys*) used in encryption and decryption operations. You can use [multiple --wrapping-keys parameters \(p. 119\)](#) in each command.

Beginning in version 2.1.x, the --wrapping-keys parameter is required in encrypt and decrypt commands. In version 1.8.x, encrypt commands require either a --wrapping-keys or --master-keys parameter. In version 1.8.x decrypt commands, a --wrapping-keys parameter is optional but recommended.

When using a custom master key provider, encrypt and decrypt commands require **key** and **provider** attributes. When using AWS KMS keys, encrypt commands require a **key** attribute. Decrypt commands require a **key** attribute or a **discovery** attribute with a value of `true` (but not both). Using the **key** attribute when decrypting is an [AWS Encryption SDK best practice \(p. 17\)](#). It is particularly important if you're decrypting batches of unfamiliar messages, such as those in an Amazon S3 bucket or an Amazon SQS queue.

For an example showing how to use AWS KMS multi-Region keys as wrapping keys, see [Use multi-Region AWS KMS keys \(p. 21\)](#).

Attributes: The value of the `--wrapping-keys` parameter consists of the following attributes. The format is `attribute_name=value`.

key

Identifies the wrapping key used in the operation. The format is a **key**=ID pair. You can specify multiple **key** attributes in each `--wrapping-keys` parameter value.

- **Encrypt commands:** All encrypt commands require the **key** attribute. When you use an AWS KMS key in an encrypt command, the value of the **key** attribute can be a key ID, key ARN, an alias name, or an alias ARN. For descriptions of the AWS KMS key identifiers, see [Key identifiers](#) in the *AWS Key Management Service Developer Guide*.
- **Decrypt commands:** When decrypting with AWS KMS keys, the `--wrapping-keys` parameter requires a **key** attribute with a [key ARN](#) value or a **discovery** attribute with a value of `true` (but not both). Using the **key** attribute is an [AWS Encryption SDK best practice \(p. 17\)](#). When decrypting with a custom master key provider, the **key** attribute is required.

Note

To specify an AWS KMS wrapping key in a decrypt command, the value of the **key** attribute must be a key ARN. If you use a key ID, alias name, or alias ARN, the AWS Encryption CLI does not recognize the wrapping key.

You can specify multiple **key** attributes in each `--wrapping-keys` parameter value. However, any **provider**, **region**, and **profile** attributes in a `--wrapping-keys` parameter apply to all wrapping keys in that parameter value. To specify wrapping keys with different attribute values, use multiple `--wrapping-keys` parameters in the command.

discovery

Allows the AWS Encryption CLI to use any AWS KMS key to decrypt the message. The **discovery** value can be `true` or `false`. The default value is `false`. The **discovery** attribute is valid only in decrypt commands and only when the master key provider is AWS KMS.

When decrypting with AWS KMS keys, the `--wrapping-keys` parameter requires a **key** attribute or a **discovery** attribute with a value of `true` (but not both). If you use the **key** attribute, you can use a **discovery** attribute with a value of `false` to explicitly reject discovery.

- `False` (default) — When the **discovery** attribute isn't specified or its value is `false`, the AWS Encryption CLI decrypts the message using only the AWS KMS keys specified by the **key** attribute of the `--wrapping-keys` parameter. If you don't specify a **key** attribute when discovery is `false`, the decrypt command fails. This value supports an [AWS Encryption CLI best practice \(p. 17\)](#).
- `True` — When the value of the **discovery** attribute is `true`, the AWS Encryption CLI gets the AWS KMS keys from metadata in the encrypted message, and uses those AWS KMS keys to decrypt the message. The **discovery** attribute with a value of `true` behaves like versions of the AWS Encryption CLI before version 1.8.x that didn't permit you to specify a wrapping key when decrypting. However, your intent to use any AWS KMS key is explicit. If you specify a **key** attribute when discovery is `true`, the decrypt command fails.

The `true` value might cause the AWS Encryption CLI to use AWS KMS keys in different AWS accounts and Regions, or attempt to use AWS KMS keys that the user isn't authorized to use.

When **discovery** is `true`, it's a best practice to use the **discovery-partition** and **discovery-account** attributes to limit the AWS KMS keys used to those in the AWS accounts you specify.

discovery-account

Limits the AWS KMS keys used for decrypting to those in the specified AWS account. The only valid value for this attribute is an [AWS account ID](#).

This attribute is optional and valid only in decrypt commands with AWS KMS keys where the **discovery** attribute is set to `true` and the **discovery-partition** attribute is specified.

Each **discovery-account** attribute takes just one AWS account ID, but you can specify multiple **discovery-account** attributes in the same `--wrapping-keys` parameter. All accounts specified in a given `--wrapping-keys` parameter must be in the specified AWS partition.

discovery-partition

Specifies the AWS partition for the accounts in the **discovery-account** attribute. Its value must be an AWS partition, such as `aws`, `aws-cn`, or `aws-gov-cloud`. For information, see [Amazon Resource Names](#) in the *AWS General Reference*.

This attribute is required when you use the **discovery-account** attribute. You can specify only one **discovery-partition** attribute in each `--wrapping-keys` parameter. To specify AWS accounts in multiple partitions, use an additional `--wrapping-keys` parameter.

provider

Identifies the [master key provider](#) (p. 7). The format is a **provider**=ID pair. The default value, **aws-kms**, represents AWS KMS. This attribute is required only when the master key provider is not AWS KMS.

region

Identifies the AWS Region of an AWS KMS key. This attribute is valid only for AWS KMS keys. It is used only when the **key** identifier does not specify a Region; otherwise, it is ignored. When it is used, it overrides the default Region in the AWS CLI named profile.

profile

Identifies an AWS CLI [named profile](#). This attribute is valid only for AWS KMS keys. The Region in the profile is used only when the key identifier does not specify a Region and there is no **region** attribute in the command.

--input (-i)

Specifies the location of the data to encrypt or decrypt. This parameter is required. The value can be a path to a file or directory, or a file name pattern. If you are piping input to the command (stdin), use `-`.

If the input does not exist, the command completes successfully without error or warning.

--recursive (-r, -R)

Performs the operation on files in the input directory and its subdirectories. This parameter is required when the value of `--input` is a directory.

--decode

Decodes Base64-encoded input.

If you are decrypting a message that was encrypted and then encoded, you must decode the message before decrypting it. This parameter does that for you.

For example, if you used the `--encode` parameter in an encrypt command, use the `--decode` parameter in the corresponding decrypt command. You can also use this parameter to decode Base64-encoded input before you encrypt it.

--output (-o)

Specifies a destination for the output. This parameter is required. The value can be a file name, an existing directory, or `-`, which writes output to the command line (stdout).

If the specified output directory does not exist, the command fails. If the input contains subdirectories, the AWS Encryption CLI reproduces the subdirectories under the output directory that you specify.

By default, the AWS Encryption CLI overwrites files with the same name. To change that behavior, use the `--interactive` or `--no-overwrite` parameters. To suppress the overwrite warning, use the `--quiet` parameter.

Note

If a command that would overwrite an output file fails, the output file is deleted.

--interactive

Prompts before overwriting the file.

--no-overwrite

Does not overwrite files. Instead, if the output file exists, the AWS Encryption CLI skips the corresponding input.

--suffix

Specifies a custom file name suffix for files that the AWS Encryption CLI creates. To indicate no suffix, use the parameter with no value (`--suffix`).

By default, when the `--output` parameter does not specify a file name, the output file name has the same name as the input file name plus the suffix. The suffix for encrypt commands is `.encrypted`. The suffix for decrypt commands is `.decrypted`.

--encode

Applies Base64 (binary to text) encoding to the output. Encoding prevents the shell host program from misinterpreting non-ASCII characters in output text.

Use this parameter when writing encrypted output to stdout (`--output -`), especially in a PowerShell console, even when you are piping the output to another command or saving it in a variable.

--metadata-output

Specifies a location for metadata about the cryptographic operations. Enter a path and file name. If the directory does not exist, the command fails. To write the metadata to the command line (stdout), use `-`.

You cannot write command output (`--output`) and metadata output (`--metadata-output`) to stdout in the same command. Also, when the value of `--input` or `--output` is a directory (without file names), you cannot write the metadata output to the same directory or to any subdirectory of that directory.

If you specify an existing file, by default, the AWS Encryption CLI appends new metadata records to any content in the file. This feature lets you create a single file that contains the metadata for all of your cryptographic operations. To overwrite the content in an existing file, use the `--overwrite-metadata` parameter.

The AWS Encryption CLI returns a JSON-formatted metadata record for each encryption or decryption operation that the command performs. Each metadata record includes the full paths to the input and output file, the encryption context, the algorithm suite, and other valuable information that you can use to review the operation and verify that it meets your security standards.

--overwrite-metadata

Overwrites the content in the metadata output file. By default, the `--metadata-output` parameter appends metadata to any existing content in the file.

--suppress-metadata (-S)

Suppresses the metadata about the encryption or decryption operation.

--commitment-policy

Specifies the [commitment policy \(p. 11\)](#) for encrypt and decrypt commands. The commitment policy determines whether your message is encrypted and decrypted with the [key commitment \(p. 10\)](#) security feature.

The `--commitment-policy` parameter is introduced in version 1.8.x. It is valid in encrypt and decrypt commands.

In version 1.8.x, the AWS Encryption CLI uses the `forbid-encrypt-allow-decrypt` commitment policy for all encrypt and decrypt operations. When you use the `--wrapping-keys` parameter in an encrypt or decrypt command, a `--commitment-policy` parameter with the `forbid-encrypt-allow-decrypt` value is required. If you don't use the `--wrapping-keys` parameter, the `--commitment-policy` parameter is invalid. Setting a commitment policy explicitly prevents your commitment policy from changing automatically to `require-encrypt-require-decrypt` when you upgrade to version 2.1.x

Beginning in **version 2.1.x**, all commitment policy values are supported. The `--commitment-policy` parameter is optional and the default value is `require-encrypt-require-decrypt`.

This parameter has the following values:

- `forbid-encrypt-allow-decrypt` — Cannot encrypt with key commitment. It can decrypt ciphertexts encrypted with or without key commitment.

In version 1.8.x, this is the only valid value. The AWS Encryption CLI uses the `forbid-encrypt-allow-decrypt` commitment policy for all encrypt and decrypt operations.

- `require-encrypt-allow-decrypt` — Encrypts only with key commitment. Decrypts with and without key commitment. This value is introduced in version 2.1.x.
- `require-encrypt-require-decrypt` (default) — Encrypts and decrypts only with key commitment. This value is introduced in version 2.1.x. It is the default value in versions 2.1.x and later. With this value, the AWS Encryption CLI will not decrypt any ciphertext that was encrypted with earlier versions of the AWS Encryption SDK.

For detailed information about setting your commitment policy, see [Migrating to versions 2.0.x and later \(p. 200\)](#).

--encryption-context (-c)

Specifies an [encryption context \(p. 121\)](#) for the operation. This parameter is not required, but it is recommended.

- In an `--encrypt` command, enter one or more `name=value` pairs. Use spaces to separate the pairs.
- In a `--decrypt` command, enter `name=value` pairs, `name` elements with no values, or both.

If the `name` or `value` in a `name=value` pair includes spaces or special characters, enclose the entire pair in quotation marks. For example, `--encryption-context "department=software development"`.

--buffer (-b) [Introduced in versions 1.9.x and 2.2.x]

Returns plaintext only after all input is processed, including verifying the digital signature if one is present.

--max-encrypted-data-keys [Introduced in versions 1.9.x and 2.2.x]

Specifies the maximum number of encrypted data keys in an encrypted message. This parameter is optional.

Valid values are 1 – 65,535. If you omit this parameter, the AWS Encryption CLI does not enforce any maximum. An encrypted message can hold up to 65,535 ($2^{16} - 1$) encrypted data keys.

You can use this parameter in encrypt commands to prevent a malformed message. You can use it in decrypt commands to detect malicious messages and avoid decrypting messages with numerous encrypted data keys that you can't decrypt. For details and an example, see [Limit encrypted data keys \(p. 41\)](#).

--help (-h)

Prints usage and syntax at the command line.

--version

Gets the version of the AWS Encryption CLI.

-v | -vv | -vvv | -vvvv

Displays verbose information, warning, and debugging messages. The detail in the output increases with the number of `vs` in the parameter. The most detailed setting (`-vvvv`) returns debugging-level data from the AWS Encryption CLI and all of the components that it uses.

--quiet (-q)

Suppresses warning messages, such as the message that appears when you overwrite an output file.

--master-keys (-m) [Deprecated]

Note

The `--master-keys` parameter is deprecated in 1.8.x and removed in version 2.1.x. Instead, use the `--wrapping-keys (p. 142)` parameter.

Specifies the [master keys \(p. 7\)](#) used in encryption and decryption operations. You can use multiple master keys parameters in each command.

The `--master-keys` parameter is required in encrypt commands. It is required in decrypt commands only when you are using a custom (non-AWS KMS) master key provider.

Attributes: The value of the `--master-keys` parameter consists of the following attributes. The format is `attribute_name=value`.

key

Identifies the [wrapping key \(p. 7\)](#) used in the operation. The format is a **key**=ID pair. The **key** attribute is required in all encrypt commands.

When you use an AWS KMS key in an encrypt command, the value of the **key** attribute can be a key ID, key ARN, an alias name, or an alias ARN. For details about AWS KMS key identifiers, see [Key identifiers](#) in the *AWS Key Management Service Developer Guide*.

The **key** attribute is required in decrypt commands when the master key provider is not AWS KMS. The **key** attribute is not permitted in commands that decrypt data that was encrypted under an AWS KMS key.

You can specify multiple **key** attributes in each `--master-keys` parameter value. However, any **provider**, **region**, and **profile** attributes apply to all master keys in the parameter value. To specify master keys with different attribute values, use multiple `--master-keys` parameters in the command.

provider

Identifies the [master key provider](#) (p. 7). The format is a **provider**=ID pair. The default value, **aws-kms**, represents AWS KMS. This attribute is required only when the master key provider is not AWS KMS.

region

Identifies the AWS Region of an AWS KMS key. This attribute is valid only for AWS KMS keys. It is used only when the **key** identifier does not specify a Region; otherwise, it is ignored. When it is used, it overrides the default Region in the AWS CLI named profile.

profile

Identifies an AWS CLI [named profile](#). This attribute is valid only for AWS KMS keys. The Region in the profile is used only when the key identifier does not specify a Region and there is no **region** attribute in the command.

Advanced parameters

--algorithm

Specifies an alternate [algorithm suite](#) (p. 9). This parameter is optional and valid only in encrypt commands.

If you omit this parameter, the AWS Encryption CLI uses one of the default algorithm suites for the AWS Encryption SDK introduced in version 1.8.x. Both default algorithms use AES-GCM with an [HKDF](#), an ECDSA signature, and a 256-bit encryption key. One uses key commitment; one does not. The choice of default algorithm suite is determined by the [commitment policy](#) (p. 11) for the command.

The default algorithm suites are recommended for most encryption operations. For a list of valid values, see the values for the `algorithm` parameter in [Read the Docs](#).

--frame-length

Creates output with specified frame length. This parameter is optional and valid only in encrypt commands.

Enter a value in bytes. Valid values are 0 and $1 - 2^{31} - 1$. A value of 0 indicates nonframed data. The default is 4096 (bytes).

Note

Whenever possible, use framed data. The AWS Encryption SDK supports nonframed data only for legacy use. Some language implementations of the AWS Encryption SDK can still generate nonframed ciphertext. All supported language implementations can decrypt framed and nonframed ciphertext.

--max-length

Indicates the maximum frame size (or maximum content length for nonframed messages) in bytes to read from encrypted messages. This parameter is optional and valid only in decrypt commands. It is designed to protect you from decrypting extremely large malicious ciphertext.

Enter a value in bytes. If you omit this parameter, the AWS Encryption SDK does not limit the frame size when decrypting.

--caching

Enables the [data key caching](#) (p. 152) feature, which reuses data keys, instead of generating a new data key for each input file. This parameter supports an advanced scenario. Be sure to read the [Data Key Caching](#) (p. 152) documentation before using this feature.

The `--caching` parameter has the following attributes.

capacity (required)

Determines the maximum number of entries in the cache.

The minimum value is 1. There is no maximum value.

max_age (required)

Determine how long cache entries are used, in seconds, beginning when they are added to the cache.

Enter a value greater than 0. There is no maximum value.

max_messages_encrypted (optional)

Determines the maximum number of messages that a cached entry can encrypt.

Valid values are 1 – 2^{32} . The default value is 2^{32} (messages).

max_bytes_encrypted (optional)

Determines the maximum number of bytes that a cached entry can encrypt.

Valid values are 0 and 1 – $2^{63} - 1$. The default value is $2^{63} - 1$ (messages). A value of 0 lets you use data key caching only when you are encrypting empty message strings.

Versions of the AWS Encryption CLI

We recommend that you use the latest version of the AWS Encryption CLI. If you're using a version of the AWS Encryption CLI older than 2.1.x, we recommend that you upgrade to version 1.8.x and then to version 2.1.x as soon as possible.

In version 2.1.x, the AWS Encryption CLI introduces support for significant new security features that meet [AWS Encryption SDK best practices \(p. 17\)](#). These new features cause breaking changes that will require updates to your commands and scripts. To make migration to version 2.1.x easier, we provide a transition version, 1.8.x that lets you prepare your commands and scripts for 2.1.x. Features that are deprecated in version 1.8.x are removed in version 2.1.x.

Note

New security features were originally released in AWS Encryption CLI versions 1.7.x and 2.0.x. However, AWS Encryption CLI version 1.8.x replaces version 1.7.x and AWS Encryption CLI 2.1.x replaces 2.0.x. For details, see the relevant [security advisory](#) in the [aws-encryption-sdk-cli](#) repository on GitHub.

For information about significant versions of the AWS Encryption SDK, see [Versions of the AWS Encryption SDK \(p. 194\)](#).

Which version do I use?

If you're new to the AWS Encryption CLI, use the latest version.

To decrypt data encrypted by a version of the AWS Encryption SDK earlier than version 1.7.x, start with version 1.8.x. Make [all recommended changes \(p. 203\)](#) before updating to version 2.1.x or later. Otherwise, you can begin with the latest available version of the AWS Encryption CLI.

Learn more

- For detailed information about the changes and guidance for migrating to these new versions, see [Migrating to versions 2.0.x and later \(p. 200\)](#).

- For descriptions of the new AWS Encryption CLI parameters and attributes, see [AWS Encryption SDK CLI syntax and parameter reference \(p. 140\)](#).

The following lists describe the change to the AWS Encryption CLI in versions 1.8.x and 2.1.x.

Version 1.8.x changes to the AWS Encryption CLI

- Deprecates the `--master-keys` parameter. Instead, use the `--wrapping-keys` parameter.
- Adds the `--wrapping-keys (-w)` parameter. It supports all attributes of the `--master-keys` parameter. It also adds the following optional attributes, which are valid only when decrypting with AWS KMS keys.
 - **discovery**
 - **discovery-partition**
 - **discovery-account**

For custom master key providers, `--encrypt` and `--decrypt` commands require either a `--wrapping-keys` parameter or a `--master-keys` parameter (but not both). Also, an `--encrypt` command with AWS KMS keys requires either a `--wrapping-keys` parameter or a `--master-keys` parameter (but not both).

In a `--decrypt` command with AWS KMS keys, the `--wrapping-keys` parameter is optional, but recommended, because it is required in version 2.1.x. If you use it, you must specify either the **key** attribute or the **discovery** attribute with a value of `true` (but not both).

- Adds the `--commitment-policy` parameter. The only valid value is `forbid-encrypt-allow-decrypt`. The `forbid-encrypt-allow-decrypt` commitment policy is used in all encrypt and decrypt commands.

In version 1.8.x, when you use the `--wrapping-keys` parameter, a `--commitment-policy` parameter with the `forbid-encrypt-allow-decrypt` value is required. Setting the value explicitly prevents your [commitment policy \(p. 11\)](#) from changing automatically to `require-encrypt-require-decrypt` when you upgrade to version 2.1.x.

Version 2.1.x changes to the AWS Encryption CLI

- Removes the `--master-keys` parameter. Instead, use the `--wrapping-keys` parameter.
- The `--wrapping-keys` parameter is required in all encrypt and decrypt commands. You must specify either a **key** attribute or a **discovery** attribute with a value of `true` (but not both).
- The `--commitment-policy` parameter supports the following values. For details, see [Setting your commitment policy \(p. 211\)](#).
 - `forbid-encrypt-allow-decrypt`
 - `require-encrypt-allow-decrypt`
 - `require-encrypt-require-decrypt` (Default)
- The `--commitment-policy` parameter is optional in version 2.1.x. The default value is `require-encrypt-require-decrypt`.

Version 1.9.x and 2.2.x changes to the AWS Encryption CLI

- Adds the `--decrypt-unsigned` parameter. For details, see [Version 2.2.x \(p. 198\)](#).
- Adds the `--buffer` parameter. For details, see [Version 2.2.x \(p. 198\)](#).
- Adds the `--max-encrypted-data-keys` parameter. For details, see [Limit encrypted data keys \(p. 41\)](#).

Version 3.0.x changes to the AWS Encryption CLI

- Adds support for AWS KMS multi-Region keys. For details, see [Use multi-Region AWS KMS keys \(p. 21\)](#).

Data key caching

Data key caching stores [data keys \(p. 6\)](#) and [related cryptographic material \(p. 173\)](#) in a cache. When you encrypt or decrypt data, the AWS Encryption SDK looks for a matching data key in the cache. If it finds a match, it uses the cached data key rather than generating a new one. Data key caching can improve performance, reduce cost, and help you stay within service limits as your application scales.

Your application can benefit from data key caching if:

- It can reuse data keys.
- It generates numerous data keys.
- Your cryptographic operations are unacceptably slow, expensive, limited, or resource-intensive.

Caching can reduce your use of cryptographic services, such as AWS Key Management Service (AWS KMS). If you are hitting your [AWS KMS requests-per-second limit](#), caching can help. Your application can use cached keys to service some of your data key requests instead of calling AWS KMS. (You can also create a case in the [AWS Support Center](#) to raise the limit for your account.)

The AWS Encryption SDK helps you to create and manage your data key cache. It provides a [local cache \(p. 172\)](#) and a [caching cryptographic materials manager \(p. 172\)](#) (caching CMM) that interacts with the cache and enforces [security thresholds \(p. 168\)](#) that you set. Working together, these components help you to benefit from the efficiency of reusing data keys while maintaining the security of your system.

Data key caching is an optional feature of the AWS Encryption SDK that you should use cautiously. By default, the AWS Encryption SDK generates a new data key for every encryption operation. This technique supports cryptographic best practices, which discourage excessive reuse of data keys. In general, use data key caching only when it is required to meet your performance goals. Then, use the data key caching [security thresholds \(p. 168\)](#) to ensure that you use the minimum amount of caching required to meet your cost and performance goals.

Data key caching is not supported by the [AWS Encryption SDK for .NET \(p. 77\)](#).

For a detailed discussion of these security tradeoffs, see [AWS Encryption SDK: How to Decide if Data Key Caching is Right for Your Application](#) in the AWS Security Blog.

Topics

- [How to use data key caching \(p. 152\)](#)
- [Setting cache security thresholds \(p. 168\)](#)
- [Data key caching details \(p. 169\)](#)
- [Data key caching example \(p. 174\)](#)

How to use data key caching

This topic shows you how to use data key caching in your application. It takes you through the process step by step. Then, it combines the steps in a simple example that uses data key caching in an operation to encrypt a string.

The examples in this section show how to use [version 2.0.x \(p. 194\)](#) and later of the AWS Encryption SDK. For examples that use earlier versions, find your release in the [Releases](#) list of the GitHub repository for your [programming language \(p. 68\)](#).

For complete and tested examples of using data key caching in the AWS Encryption SDK, see:

- C/C++: [caching_cmm.cpp](#)
- Java: [SimpleDataKeyCachingExample.java](#)
- JavaScript Browser: [caching_cmm.ts](#)
- JavaScript Node.js: [caching_cmm.ts](#)
- Python: [data_key_caching_basic.py](#)

The [AWS Encryption SDK for .NET \(p. 77\)](#) does not support data key caching.

Topics

- [Using data key caching: Step-by-step \(p. 153\)](#)
- [Data key caching example: Encrypt a string \(p. 158\)](#)

Using data key caching: Step-by-step

These step-by-step instructions show you how to create the components that you need to implement data key caching.

- [Create a data key cache \(p. 172\)](#). In these examples, we use the local cache that the AWS Encryption SDK provides. We limit the cache to 10 data keys.

C

```
// Cache capacity (maximum number of entries) is required
size_t cache_capacity = 10;
struct aws_allocator *allocator = aws_default_allocator();

struct aws_cryptosdk_materials_cache *cache =
    aws_cryptosdk_materials_cache_local_new(allocator, cache_capacity);
```

Java

```
// Cache capacity (maximum number of entries) is required
int MAX_CACHE_SIZE = 10;

CryptoMaterialsCache cache = new LocalCryptoMaterialsCache(MAX_CACHE_SIZE);
```

JavaScript Browser

```
const capacity = 10

const cache = getLocalCryptographicMaterialsCache(capacity)
```

JavaScript Node.js

```
const capacity = 10

const cache = getLocalCryptographicMaterialsCache(capacity)
```

Python

```
# Cache capacity (maximum number of entries) is required
MAX_CACHE_SIZE = 10
```

```
cache = aws_encryption_sdk.LocalCryptoMaterialsCache(MAX_CACHE_SIZE)
```

- Create a [master key provider \(p. 7\)](#) (Java and Python) or a [keyring \(p. 7\)](#) (C and JavaScript). These examples use an AWS Key Management Service (AWS KMS) master key provider or a compatible [AWS KMS keyring \(p. 49\)](#).

C

```
// Create an AWS KMS keyring
//   The input is the Amazon Resource Name (ARN)
//   of an AWS KMS key

struct aws_cryptosdk_keyring *kms_keyring =
    Aws::Cryptosdk::KmsKeyring::Builder().Build(kms_key_arn);
```

Java

```
// Create an AWS KMS master key provider
//   The input is the Amazon Resource Name (ARN)
//   of an AWS KMS key

MasterKeyProvider<KmsMasterKey> keyProvider =
    KmsMasterKeyProvider.builder().buildStrict(kmsKeyArn);
```

JavaScript Browser

In the browser, you must inject your credentials securely. This example defines credentials in a webpack (`kms.webpack.config`) that resolves credentials at runtime. It creates an AWS KMS client provider instance from an AWS KMS client and the credentials. Then, when it creates the keyring, it passes the client provider to the constructor along with the AWS KMS key (`generatorKeyId`).

```
const { accessKeyId, secretAccessKey, sessionToken } = credentials

const clientProvider = getClient(KMS, {
  credentials: {
    accessKeyId,
    secretAccessKey,
    sessionToken
  }
})

/* Create an AWS KMS keyring
 * You must configure the AWS KMS keyring with at least one AWS KMS key
 * The input is the Amazon Resource Name (ARN)
 */ of an AWS KMS key

const keyring = new KmsKeyringBrowser({
  clientProvider,
  generatorKeyId,
  keyIds,
})
```

JavaScript Node.js

```
/* Create an AWS KMS keyring
 *   The input is the Amazon Resource Name (ARN)
```

```
*/    of an AWS KMS key

const keyring = new KmsKeyringNode({ generatorKeyId })
```

Python

```
# Create an AWS KMS master key provider
# The input is the Amazon Resource Name (ARN)
# of an AWS KMS key

key_provider =
    aws_encryption_sdk.StrictAwsKmsMasterKeyProvider(key_ids=[kms_key_arn])
```

- [Create a caching cryptographic materials manager \(p. 172\)](#) (caching CMM).

Associate your caching CMM with your cache and your master key provider or keyring. Then, [set cache security thresholds \(p. 168\)](#) on the caching CMM.

C

In the AWS Encryption SDK for C, you can create a caching CMM from an underlying CMM, such as the default CMM, or from a keyring. This example creates the caching CMM from a keyring.

After you create the caching CMM, you can release your references to the keyring and the cache. For details, see [the section called “Reference counting” \(p. 71\)](#).

```
// Create the caching CMM
// Set the partition ID to NULL.
// Set the required maximum age value to 60 seconds.
struct aws_cryptosdk_cmm *caching_cmm =
    aws_cryptosdk_caching_cmm_new_from_keyring(allocator, cache, kms_keyring, NULL, 60,
        AWS_TIMESTAMP_SECS);

// Add an optional message threshold
// The cached data key will not be used for more than 10 messages.
aws_status = aws_cryptosdk_caching_cmm_set_limit_messages(caching_cmm, 10);

// Release your references to the cache and the keyring.
aws_cryptosdk_materials_cache_release(cache);
aws_cryptosdk_keyring_release(kms_keyring);
```

Java

```
/*
 * Security thresholds
 * Max entry age is required.
 * Max messages (and max bytes) per entry are optional
 */
int MAX_ENTRY_AGE_SECONDS = 60;
int MAX_ENTRY_MSGS = 10;

//Create a caching CMM
CryptoMaterialsManager cachingCmm =
    CachingCryptoMaterialsManager.newBuilder().withMasterKeyProvider(keyProvider)
        .withCache(cache)
        .withMaxAge(MAX_ENTRY_AGE_SECONDS, TimeUnit.SECONDS)
```

```
.withMessageUseLimit(MAX_ENTRY_MSGS)
.build();
```

JavaScript Browser

```
/*
 * Security thresholds
 *   Max age (in milliseconds) is required.
 *   Max messages (and max bytes) per entry are optional.
 */
const maxAge = 1000 * 60
const maxMessagesEncrypted = 10

/* Create a caching CMM from a keyring */
const cachingCmm = new WebCryptoCachingMaterialsManager({
  backingMaterials: keyring,
  cache,
  maxAge,
  maxMessagesEncrypted
})
```

JavaScript Node.js

```
/*
 * Security thresholds
 *   Max age (in milliseconds) is required.
 *   Max messages (and max bytes) per entry are optional.
 */
const maxAge = 1000 * 60
const maxMessagesEncrypted = 10

/* Create a caching CMM from a keyring */
const cachingCmm = new NodeCachingMaterialsManager({
  backingMaterials: keyring,
  cache,
  maxAge,
  maxMessagesEncrypted
})
```

Python

```
# Security thresholds
#   Max entry age is required.
#   Max messages (and max bytes) per entry are optional
#
MAX_ENTRY_AGE_SECONDS = 60.0
MAX_ENTRY_MESSAGES = 10

# Create a caching CMM
caching_cmm = CachingCryptoMaterialsManager(
    master_key_provider=key_provider,
    cache=cache,
    max_age=MAX_ENTRY_AGE_SECONDS,
    max_messages_encrypted=MAX_ENTRY_MESSAGES
)
```

That's all you need to do. Then, let the AWS Encryption SDK manage the cache for you, or add your own cache management logic.

When you want to use data key caching in a call to encrypt or decrypt data, specify your caching CMM instead of a master key provider or other CMM.

Note

If you are encrypting data streams, or any data of unknown size, be sure to specify the data size in the request. The AWS Encryption SDK does not use data key caching when encrypting data of unknown size.

C

In the AWS Encryption SDK for C, you create a session with the caching CMM and then process the session.

By default, when the message size is unknown and unbounded, the AWS Encryption SDK does not cache data keys. To allow caching when you don't know the exact data size, use the `aws_cryptosdk_session_set_message_bound` method to set a maximum size for the message. Set the bound larger than the estimated message size. If the actual message size exceeds the bound, the encryption operation fails.

```
/* Create a session with the caching CMM. Set the session mode to encrypt. */
struct aws_cryptosdk_session *session = aws_cryptosdk_session_new_from_cmm_2(allocator,
    AWS_CRYPTOSDK_ENCRYPT, caching_cmm);

/* Set a message bound of 1000 bytes */
aws_status = aws_cryptosdk_session_set_message_bound(session, 1000);

/* Encrypt the message using the session with the caching CMM */
aws_status = aws_cryptosdk_session_process(
    session, output_buffer, output_capacity, &output_produced, input_buffer,
    input_len, &input_consumed);

/* Release your references to the caching CMM and the session. */
aws_cryptosdk_cmm_release(caching_cmm);
aws_cryptosdk_session_destroy(session);
```

Java

```
// When the call to encryptData specifies a caching CMM,
// the encryption operation uses the data key cache
final AwsCrypto encryptionSdk = AwsCrypto.standard();
return encryptionSdk.encryptData(cachingCmm, plaintext_source).getResult();
```

JavaScript Browser

```
const { result } = await encrypt(cachingCmm, plaintext)
```

JavaScript Node.js

When you use the caching CMM in the AWS Encryption SDK for JavaScript for Node.js, the `encrypt` method requires the length of the plaintext. If you don't provide it, the data key is not cached. If you provide a length, but the plaintext data that you supply exceeds that length, the encrypt operation fails. If you don't know the exact length of the plaintext, such as when you're streaming data, provide the largest expected value.

```
const { result } = await encrypt(cachingCmm, plaintext, { plaintextLength:
    plaintext.length })
```

Python

```
# Set up an encryption client
```

```
client = aws_encryption_sdk.EncryptionSDKClient()

# When the call to encrypt specifies a caching CMM,
# the encryption operation uses the data key cache
#
encrypted_message, header = client.encrypt(
    source=plaintext_source,
    materials_manager=caching_cmm
)
```

Data key caching example: Encrypt a string

This simple code example uses data key caching when encrypting a string. It combines the code from the [step-by-step procedure \(p. 153\)](#) into test code that you can run.

The example creates a [local cache \(p. 172\)](#) and a [master key provider \(p. 7\)](#) or [keyring \(p. 7\)](#) for an AWS KMS key. Then, it uses the local cache and master key provider or keyring to create a caching CMM with appropriate [security thresholds \(p. 168\)](#). In Java and Python, the encryption request specifies the caching CMM, the plaintext data to encrypt, and an [encryption context \(p. 173\)](#). In C, the caching CMM is specified in the session, and the session is provided to the encryption request.

To run these examples, you need to supply the [Amazon Resource Name \(ARN\) of an AWS KMS key](#). Be sure that you have [permission to use the AWS KMS key](#) to generate a data key.

For more detailed, real-world examples of creating and using a data key cache, see [Data key caching example code \(p. 176\)](#).

return encrypted_message
```

Setting cache security thresholds

When you implement data key caching, you need to configure the security thresholds that the [caching CMM \(p. 172\)](#) enforces.

The security thresholds help you to limit how long each cached data key is used and how much data is protected under each data key. The caching CMM returns cached data keys only when the cache entry conforms to all of the security thresholds. If the cache entry exceeds any threshold, the entry is not used for the current operation and it is evicted from the cache as soon as possible. The first use of each data key (before caching) is exempt from these thresholds.

As a rule, use the minimum amount of caching that is required to meet your cost and performance goals.

The AWS Encryption SDK only caches data keys that are encrypted by using a [key derivation function](#). Also, it establishes upper limits for some of the threshold values. These restrictions ensure that data keys are not reused beyond their cryptographic limits. However, because your plaintext data keys are cached (in memory, by default), try to minimize the time that the keys are saved. Also, try to limit the data that might be exposed if a key is compromised.

For examples of setting cache security thresholds, see [AWS Encryption SDK: How to Decide if Data Key Caching is Right for Your Application](#) in the AWS Security Blog.

Note

The caching CMM enforces all of the following thresholds. If you do not specify an optional value, the caching CMM uses the default value.

To disable data key caching temporarily, the Java and Python implementations of the AWS Encryption SDK provide a *null cryptographic materials cache* (null cache). The null cache returns a miss for every `GET` request and does not respond to `PUT` requests. We recommend that you use the null cache instead of setting the [cache capacity \(p. 172\)](#) or security thresholds to 0. For more information, see the null cache in [Java](#) and [Python](#).

Maximum age (required)

Determines how long a cached entry can be used, beginning when it was added. This value is required. Enter a value greater than 0. The AWS Encryption SDK does not limit the maximum age value.

All language implementations of the AWS Encryption SDK define the maximum age in seconds, except for the AWS Encryption SDK for JavaScript, which uses milliseconds.

Use the shortest interval that still allows your application to benefit from the cache. You can use the maximum age threshold like a key rotation policy. Use it to limit reuse of data keys, minimize exposure of cryptographic materials, and evict data keys whose policies might have changed while they were cached.

Maximum messages encrypted (optional)

Specifies the maximum number of messages that a cached data key can encrypt. This value is optional. Enter a value between 1 and 2^{32} messages. The default value is 2^{32} messages.

Set the number of messages protected by each cached key to be large enough to get value from reuse, but small enough to limit the number of messages that might be exposed if a key is compromised.

Maximum bytes encrypted (optional)

Specifies the maximum number of bytes that a cached data key can encrypt. This value is optional. Enter a value between 0 and $2^{63} - 1$. The default value is $2^{63} - 1$. A value of 0 lets you use data key caching only when you are encrypting empty message strings.

The bytes in the current request are included when evaluating this threshold. If the bytes processed, plus current bytes, exceed the threshold, the cached data key is evicted from the cache, even though it might have been used on a smaller request.

Data key caching details

Most applications can use the default implementation of data key caching without writing custom code. This section describes the default implementation and some details about options.

Topics

- [Is my application using cached data keys? \(p. 174\)](#)

How data key caching works

When you use data key caching in a request to encrypt or decrypt data, the AWS Encryption SDK first searches the cache for a data key that matches the request. If it finds a valid match, it uses the cached data key to encrypt the data. Otherwise, it generates a new data key, just as it would without the cache.

Data key caching is not used for data of unknown size, such as streamed data. This allows the caching CMM to properly enforce the [maximum bytes threshold \(p. 168\)](#). To avoid this behavior, add the message size to the encryption request.

In addition to a cache, data key caching uses a [caching cryptographic materials manager \(p. 172\)](#) (caching CMM). The caching CMM is a specialized [cryptographic materials manager \(CMM\) \(p. 9\)](#) that interacts with a [cache \(p. 172\)](#) and an underlying [CMM \(p. 9\)](#). (When you specify a [master key provider \(p. 7\)](#) or keyring, the AWS Encryption SDK creates a default CMM for you.) The caching CMM caches the data keys that its underlying CMM returns. The caching CMM also enforces cache security thresholds that you set.

To prevent the wrong data key from being selected from the cache, all compatible caching CMMs require that the following properties of the cached cryptographic materials match the materials request.

- [Algorithm suite \(p. 9\)](#)
- [Encryption context \(p. 173\)](#) (even when empty)
- Partition name (a string that identifies the caching CMM)
- (Decryption only) Encrypted data keys

Note

The AWS Encryption SDK caches data keys only when the [algorithm suite \(p. 9\)](#) uses a [key derivation function](#).

The following workflows show how a request to encrypt data is processed with and without data key caching. They show how the caching components that you create, including the cache and the caching CMM, are used in the process.

Encrypt data without caching

To get encryption materials without caching:

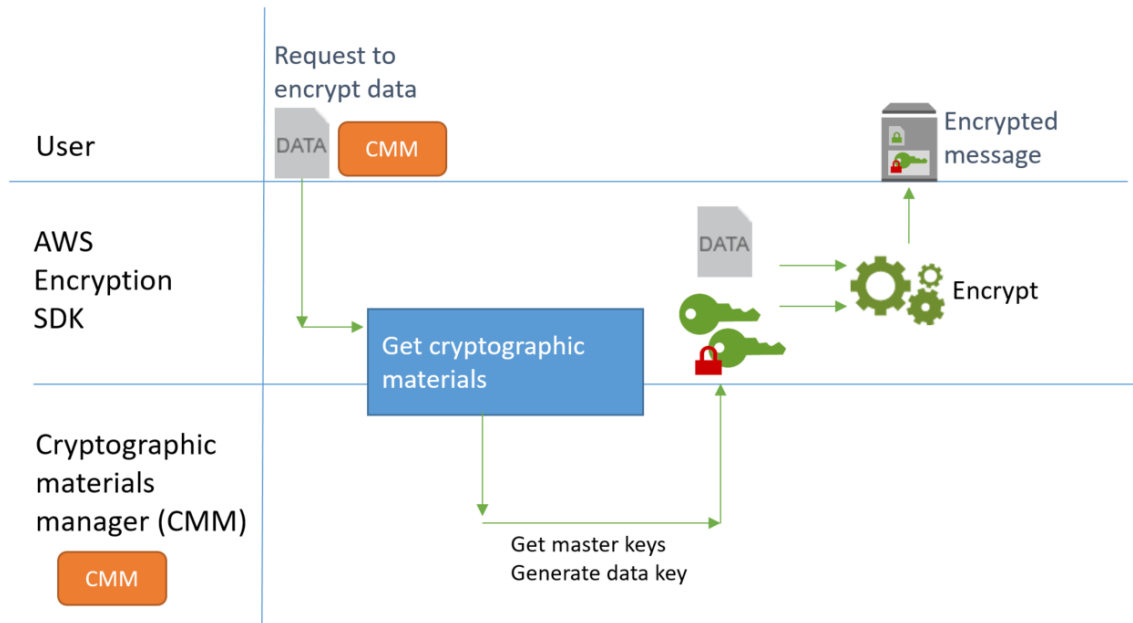

1. An application asks the AWS Encryption SDK to encrypt data.

The request specifies a master key provider or keyring. The AWS Encryption SDK creates a default CMM that interacts with your master key provider or keyring.

2. The AWS Encryption SDK asks the CMM for encryption materials (get cryptographic materials).
3. The CMM asks its [keyring \(p. 7\)](#) (C and JavaScript) or [master key provider \(p. 7\)](#) (Java and Python) for cryptographic materials. This might involve a call to a cryptographic service, such as AWS Key

Management Service (AWS KMS). The CMM returns the encryption materials to the AWS Encryption SDK.

4. The AWS Encryption SDK uses the plaintext data key to encrypt the data. It stores the encrypted data and encrypted data keys in an [encrypted message \(p. 8\)](#), which it returns to the user.

Encrypt data with caching

To get encryption materials with data key caching:

1. An application asks the AWS Encryption SDK to encrypt data.

The request specifies a [caching cryptographic materials manager \(caching CMM\) \(p. 172\)](#) that is associated with a underlying cryptographic materials manager (CMM). When you specify a master key provider or keyring, the AWS Encryption SDK creates a default CMM for you.

2. The SDK asks the specified caching CMM for encryption materials.
3. The caching CMM requests encryption materials from the cache.

- a. If the cache finds a match, it updates the age and use values of the matched cache entry, and returns the cached encryption materials to the caching CMM.

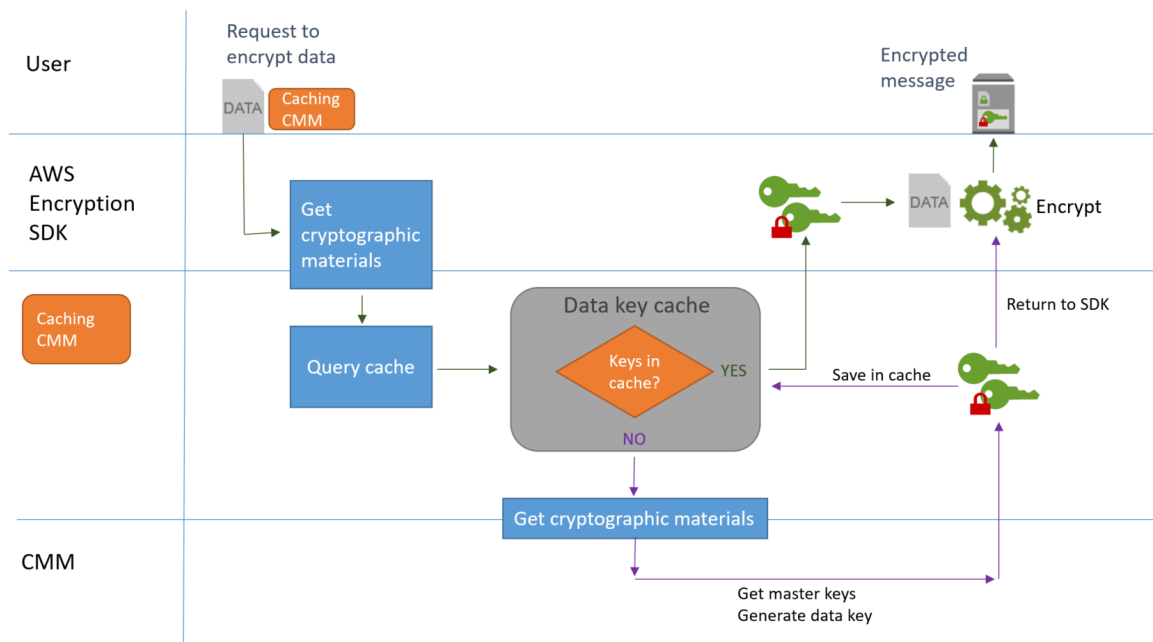

If the cache entry conforms to its [security thresholds \(p. 168\)](#), the caching CMM returns it to the SDK. Otherwise, it tells the cache to evict the entry and proceeds as though there was no match.

- b. If the cache cannot find a valid match, the caching CMM asks its underlying CMM to generate a new data key.

The underlying CMM gets the cryptographic materials from its keyring (C and JavaScript) or master key provider (Java and Python). This might involve a call to a service, such as AWS Key Management Service. The underlying CMM returns the plaintext and encrypted copies of the data key to the caching CMM.

The caching CMM saves the new encryption materials in the cache.

4. The caching CMM returns the encryption materials to the AWS Encryption SDK.
5. The AWS Encryption SDK uses the plaintext data key to encrypt the data. It stores the encrypted data and encrypted data keys in an [encrypted message \(p. 8\)](#), which it returns to the user.

Creating a cryptographic materials cache

The AWS Encryption SDK defines the requirements for a cryptographic materials cache used in data key caching. It also provides a local cache, which is a configurable, in-memory, [least recently used \(LRU\) cache](#). To create an instance of the local cache, use the `LocalCryptoMaterialsCache` constructor in Java and Python, the `getLocalCryptographicMaterialsCache` function in JavaScript, or the `aws_cryptosdk_materials_cache_local_new` constructor in C.

The local cache includes logic for basic cache management, including adding, evicting, and matching cached entries, and maintaining the cache. You don't need to write any custom cache management logic. You can use the local cache as is, customize it, or substitute any compatible cache.

When you create a local cache, you set its *capacity*, that is, the maximum number of entries that the cache can hold. This setting helps you to design an efficient cache with limited data key reuse.

The AWS Encryption SDK for Java and the AWS Encryption SDK for Python also provide a *null cryptographic materials cache* (`NullCryptoMaterialsCache`). The `NullCryptoMaterialsCache` returns a miss for all `GET` operations and does not respond to `PUT` operations. You can use the `NullCryptoMaterialsCache` in testing or to temporarily disable caching in an application that includes caching code.

In the AWS Encryption SDK, each cryptographic materials cache is associated with a [caching cryptographic materials manager \(p. 172\)](#) (caching CMM). The caching CMM gets data keys from the cache, puts data keys in the cache, and enforces [security thresholds \(p. 168\)](#) that you set. When you create a caching CMM, you specify the cache that it uses and the underlying CMM or master key provider that generates the data keys that it caches.

Creating a caching cryptographic materials manager

To enable data key caching, you create a [cache \(p. 172\)](#) and a *caching cryptographic materials manager* (caching CMM). Then, in your requests to encrypt or decrypt data, you specify a caching CMM, instead of a standard [cryptographic materials manager \(CMM\) \(p. 9\)](#), or [master key provider \(p. 7\)](#) or [keyring \(p. 7\)](#).

There are two types of CMMs. Both get data keys (and related cryptographic material), but in different ways, as follows:

- A CMM is associated with a keyring (C or JavaScript) or a master key provider (Java and Python). When the SDK asks the CMM for encryption or decryption materials, the CMM gets the materials from its keyring or master key provider. In Java and Python, the CMM uses the master keys to generate, encrypt, or decrypt the data keys. In C and JavaScript, the keyring generates, encrypts, and returns the cryptographic materials.
- A caching CMM is associated with one cache, such as a [local cache \(p. 172\)](#), and an underlying CMM. When the SDK asks the caching CMM for cryptographic materials, the caching CMM tries to get them from the cache. If it cannot find a match, the caching CMM asks its underlying CMM for the materials. Then, it caches the new cryptographic materials before returning them to the caller.

The caching CMM also enforces [security thresholds \(p. 168\)](#) that you set for each cache entry. Because the security thresholds are set in and enforced by the caching CMM, you can use any compatible cache, even if the cache is not designed for sensitive material.

What is in a data key cache entry?

Data key caching stores data keys and related cryptographic materials in a cache. Each entry includes the elements listed below. You might find this information useful when you're deciding whether to use the data key caching feature, and when you're setting security thresholds on a caching cryptographic materials manager (caching CMM).

Cached Entries for Encryption Requests

The entries that are added to a data key cache as a result of an encryption operation include the following elements:

- Plaintext data key
- Encrypted data keys (one or more)
- [Encryption context \(p. 173\)](#)
- Message signing key (if one is used)
- [Algorithm suite \(p. 9\)](#)
- Metadata, including usage counters for enforcing security thresholds

Cached Entries for Decryption Requests

The entries that are added to a data key cache as a result of a decryption operation include the following elements:

- Plaintext data key
- Signature verification key (if one is used)
- Metadata, including usage counters for enforcing security thresholds

Encryption context: How to select cache entries

You can specify an encryption context in any request to encrypt data. However, the encryption context plays a special role in data key caching. It lets you create subgroups of data keys in your cache, even when the data keys originate from the same caching CMM.

An [encryption context \(p. 8\)](#) is a set of key-value pairs that contain arbitrary nonsecret data. During encryption, the encryption context is cryptographically bound to the encrypted data so that the same encryption context is required to decrypt the data. In the AWS Encryption SDK, the encryption context is stored in the [encrypted message \(p. 8\)](#) with the encrypted data and data keys.

When you use a data key cache, you can also use the encryption context to select particular cached data keys for your encryption operations. The encryption context is saved in the cache entry with the data key (it's part of the cache entry ID). Cached data keys are reused only when their encryption contexts match. If you want to reuse certain data keys for an encryption request, specify the same encryption context. If you want to avoid those data keys, specify a different encryption context.

The encryption context is always optional, but recommended. If you don't specify an encryption context in your request, an empty encryption context is included in the cache entry identifier and matched to each request.

Is my application using cached data keys?

Data key caching is an optimization strategy that is very effective for certain applications and workloads. However, because it entails some risk, it's important to determine how effective it is likely to be for your situation, and then decide whether the benefits outweigh the risks.

Because data key caching reuses data keys, the most obvious effect is reducing the number of calls to generate new data keys. When data key caching is implemented, the AWS Encryption SDK calls the AWS KMS `GenerateDataKey` operation only to create the initial data key and when the cache misses. But, caching improves performance perceptibly only in applications that generate numerous data keys with the same characteristics, including the same encryption context and algorithm suite.

To determine whether your implementation of the AWS Encryption SDK is actually using data keys from the cache, try the following techniques.

- In the logs of your master key infrastructure, check the frequency of calls to create new data keys. When data key caching is effective, the number of calls to create new keys should drop perceptibly. For example, if you are using a AWS KMS master key provider or keyring, search the CloudTrail logs for [GenerateDataKey](#) calls.
- Compare the [encrypted messages \(p. 8\)](#) that the AWS Encryption SDK returns in response to different encrypt requests. For example, if you are using the AWS Encryption SDK for Java, compare the [ParsedCiphertext](#) object from different encrypt calls. In the AWS Encryption SDK for JavaScript, compare the contents of the `encryptedDataKeys` property of the [MessageHeader](#). When data keys are reused, the encrypted data keys in the encrypted message are identical.

Data key caching example

This example uses [data key caching \(p. 152\)](#) with a [local cache \(p. 172\)](#) to speed up an application in which data generated by multiple devices is encrypted and stored in different Regions.

In this scenario, multiple data producers generate data, encrypt it, and write to a [Kinesis stream](#) in each Region. [AWS Lambda](#) functions (consumers) decrypt the streams and write plaintext data to a DynamoDB table in the Region. Data producers and consumers use the AWS Encryption SDK and an [AWS KMS master key provider \(p. 7\)](#). To reduce calls to KMS, each producer and consumer has their own local cache.

You can find the source code for these examples in [Java and Python \(p. 176\)](#). The sample also includes a AWS CloudFormation template that defines the resources for the samples.

Local cache results

The following table shows that a local cache reduces the total calls to KMS (per second per Region) in this example to 1% of its original value.

Producer requests

	Requests per second per client			Clients per region	Average requests per second per region
	Generate data key (us-west-2)	Encrypt data key (eu-central-1)	Total (per region)		
No cache	1	1	1	500	500
Local cache	1 rps / 100 uses	1 rps / 100 uses	1 rps / 100 uses	500	5

Consumer requests

	Requests per second per client			Client per region	Average requests per second per region
	Decrypt data key	Producers	Total		
No cache	1 rps per producer	500	500	2	1,000
Local cache	1 rps per producer / 100 uses	500	5	2	10

Data key caching example code

This code sample creates a simple implementation of data key caching with a [local cache \(p. 172\)](#) in Java and Python. The code creates two instances of a local cache: one for [data producers \(p. 176\)](#) that are encrypting data and another for [data consumers \(p. 180\)](#) (AWS Lambda functions) that are decrypting data. For details about the implementation of data key caching in each language, see the [Javadoc](#) and [Python documentation](#) for the AWS Encryption SDK.

Data key caching is available for all [programming languages \(p. 68\)](#) that the AWS Encryption SDK supports.

For complete and tested examples of using data key caching in the AWS Encryption SDK, see:

- C/C++: [caching_cmm.cpp](#)
- Java: [SimpleDataKeyCachingExample.java](#)
- JavaScript Browser: [caching_cmm.ts](#)
- JavaScript Node.js: [caching_cmm.ts](#)
- Python: [data_key_caching_basic.py](#)

Producer

The producer gets a map, converts it to JSON, uses the AWS Encryption SDK to encrypt it, and pushes the ciphertext record to a [Kinesis stream](#) in each AWS Region.

The code defines a [caching cryptographic materials manager \(p. 172\)](#) (caching CMM) and associates it with a [local cache \(p. 172\)](#) and an underlying [AWS KMS master key provider \(p. 7\)](#). The caching CMM caches the data keys (and [related cryptographic materials \(p. 173\)](#)) from the master key provider. It also interacts with the cache on behalf of the SDK and enforces security thresholds that you set.

Because the call to the encrypt method specifies a caching CMM, instead of a regular [cryptographic materials manager \(CMM\) \(p. 9\)](#) or master key provider, the encryption will use data key caching.

```

Consumer

The data consumer is an [AWS Lambda](#) function that is triggered by [Kinesis](#) events. It decrypts and deserializes each record, and writes the plaintext record to an [Amazon DynamoDB](#) table in the same Region.

Like the producer code, the consumer code enables data key caching by using a caching cryptographic materials manager (caching CMM) in calls to the decrypt method.

The Java code builds a master key provider in *strict mode* with a specified AWS KMS key. Strict mode isn't required when decrypting, but it's a [best practice \(p. 18\)](#). The Python code uses *discovery mode*, which lets the AWS Encryption SDK use any wrapping key that encrypted a data key to decrypt it.

Java

This code creates a master key provider for decrypting in strict mode. The AWS Encryption SDK can use only the AWS KMS keys you specify to decrypt your message.

Versions of the AWS Encryption SDK

The AWS Encryption SDK language implementations use [semantic versioning](#) to make it easier for you to identify the magnitude of changes in each release. A change in the major version number, such as 1.x.x to 2.x.x, indicates a breaking change that is likely to require code changes and a planned deployment. A change in a minor version, such as x.1.x to x.2.x, is always backward compatible, but might include deprecated elements.

Whenever possible, use the latest version of the AWS Encryption SDK in your chosen programming language. The [maintenance and support policy](#) (p. 3) for each version differs between programming language implementations. For details about the supported versions in your preferred programming language, see the `SUPPORT_POLICY.rst` file in its [GitHub repository](#) (p. 2).

When upgrades include new features that require special configuration to avoid encryption or decryption error, we provide an intermediate version and detailed instructions for using it. For example, versions 1.7.x and 1.8.x are designed to be transitional versions that help you upgrade from versions earlier than 1.7.x to versions 2.0.x and later. For details, see [Migrating to AWS Encryption SDK Versions 2.0.x and later](#) (p. 200).

For a detailed description of the changes for each version your programming language, see the Changelog for each repository.

- AWS Encryption SDK for C — [CHANGELOG.md](#)
- C# / .NET — [CHANGELOG.md](#)
- AWS Encryption CLI — [Versions of the AWS Encryption CLI](#) (p. 149) and [CHANGELOG.rst](#)
- AWS Encryption SDK for Java — [CHANGELOG.md](#)
- AWS Encryption SDK for JavaScript — [CHANGELOG.md](#)
- AWS Encryption SDK for Python — [CHANGELOG.rst](#)

Note

The x in a version number represents any patch of the major and minor version. For example, version 1.7.x represents all versions that begin with 1.7, including 1.7.1 and 1.7.9. New security features were originally released in AWS Encryption CLI versions 1.7.x and 2.0.x. However, AWS Encryption CLI version 1.8.x replaces version 1.7.x and AWS Encryption CLI 2.1.x replaces 2.0.x. For details, see the relevant [security advisory](#) in the [aws-encryption-sdk-cli](#) repository on GitHub.

The following list describes the major differences between supported versions of the AWS Encryption SDK.

Topics

- [Versions earlier than 1.7.x](#) (p. 195)
- [Version 1.7.x](#) (p. 195)
- [Version 1.8.x](#) (p. 197)
- [Version 1.9.x](#) (p. 197)
- [Version 2.0.x](#) (p. 197)
- [Version 2.1.x](#) (p. 198)
- [Version 2.2.x](#) (p. 198)

- [Version 2.3.x \(p. 199\)](#)
- [Version 2.4.x \(p. 199\)](#)
- [Version 3.0.x \(p. 199\)](#)

Versions earlier than 1.7.x

Note

All 1.x.x versions of the AWS Encryption SDK are in the [end-of-support phase](#) effective July 2022. Upgrade to the latest available version of the AWS Encryption SDK for your programming language as soon as is practical. To upgrade from an AWS Encryption SDK version earlier than 1.7.x, you must first upgrade to 1.7.x. For details, see [Migrating to AWS Encryption SDK Versions 2.0.x and later \(p. 200\)](#).

Versions of the AWS Encryption SDK earlier than 1.7.x provide important security features, including encryption with the Advanced Encryption Standard algorithm in Galois/Counter Mode (AES-GCM), an HMAC-based extract-and-expand key derivation function (HKDF), signing, and a 256-bit encryption key. However, these versions don't support [best practices \(p. 17\)](#) that we recommend, including [key commitment \(p. 10\)](#).

Version 1.7.x

Note

All 1.x.x versions of the AWS Encryption SDK are in the [end-of-support phase](#) effective July 2022.

Version 1.7.x is designed to help users of earlier versions of the AWS Encryption SDK to upgrade to versions 2.0.x and later. If you are new to the AWS Encryption SDK, you can skip this version and begin with the latest available version in your programming language.

Version 1.7.x is fully backward compatible; it does not introduce any breaking changes or change the behavior of the AWS Encryption SDK. It's also forwards compatible; it allows you to update your code so it's compatible with version 2.0.x. It includes new features, but doesn't fully enable them. And it requires configuration values that prevent you from immediately adopting all new features until you are ready.

Version 1.7.x includes the following changes:

AWS KMS master key provider updates (required)

Version 1.7.x introduces new constructors to the AWS Encryption SDK for Java and AWS Encryption SDK for Python that explicitly create AWS KMS master key providers in either *strict* or *discovery* mode. This version adds similar changes to the AWS Encryption SDK command-line interface (CLI). For details, see [Updating AWS KMS master key providers \(p. 204\)](#).

- In *strict mode*, AWS KMS master key providers require a list of wrapping keys, and they encrypt and decrypt with only the wrapping keys you specify. This is an AWS Encryption SDK best practice that assures that you are using the wrapping keys you intend to use.
- In *discovery mode*, AWS KMS master key providers do not take any wrapping keys. You cannot use them for encrypting. When decrypting, they can use any wrapping key to decrypt an encrypted data key. However, you can limit the wrapping keys used for decryption to those in particular AWS accounts. Account filtering is optional, but it's a [best practice \(p. 17\)](#) that we recommend.

The constructors that create earlier versions of AWS KMS master key providers are deprecated in version 1.7.x and removed in version 2.0.x. These constructors instantiate master key providers that encrypt using the wrapping keys you specify. However, they decrypt encrypted data keys using the

wrapping key that encrypted them, without regard to the specified wrapping keys. Users might unintentionally decrypt messages with wrapping keys they don't intend to use, including AWS KMS keys in other AWS accounts and Regions.

There are no changes to constructors for AWS KMS master keys. When encrypting and decrypting, AWS KMS master keys use only the AWS KMS key that you specify.

AWS KMS keyring updates (optional)

Version 1.7.x adds a new filter to the AWS Encryption SDK for C and AWS Encryption SDK for JavaScript implementations that limits [AWS KMS discovery keyrings \(p. 55\)](#) to particular AWS accounts. This new account filter is optional, but it's a [best practice \(p. 17\)](#) that we recommend. For details, see [Updating AWS KMS keyrings \(p. 209\)](#).

There are no changes to constructors for AWS KMS keyrings. Standard AWS KMS keyrings behave like master key providers in strict mode. AWS KMS discovery keyrings are created explicitly in discovery mode.

Passing a key ID to AWS KMS Decrypt

Beginning in version 1.7.x, when decrypting encrypted data keys, the AWS Encryption SDK always specifies an AWS KMS key in its calls to the AWS KMS [Decrypt](#) operation. The AWS Encryption SDK gets the key ID value for the AWS KMS key from the metadata in each encrypted data key. This feature doesn't require any code changes.

Specifying the key ID of the AWS KMS key is not required to decrypt ciphertext that was encrypted under a symmetric encryption KMS key, but it is an [AWS KMS best practice](#). Like specifying wrapping keys in your key provider, this practice assures that AWS KMS only decrypts using the wrapping key you intend to use.

Decrypt ciphertext with key commitment

Version 1.7.x can decrypt ciphertext that was encrypted with or without [key commitment \(p. 10\)](#). However, it cannot encrypt ciphertext with key commitment. This property allows you to fully deploy applications that can decrypt ciphertext encrypted with key commitment before they ever encounter any such ciphertext. Because this version decrypts messages that are encrypted without key commitment, you don't need to re-encrypt any ciphertext.

To implement this behavior, version 1.7.x includes a new [commitment policy \(p. 11\)](#) configuration setting that determines whether the AWS Encryption SDK can encrypt or decrypt with key commitment. In version 1.7.x, the only valid value for the commitment policy, `ForbidEncryptAllowDecrypt`, is used in all encrypt and decrypt operations. This value prevents the AWS Encryption SDK from encrypting with either of the new algorithm suites that include key commitment. It allows the AWS Encryption SDK to decrypt ciphertext with and without key commitment.

Although there is only one valid commitment policy value in version 1.7.x, we require that you can set this value explicitly when you use the new APIs introduced in this release. Setting the value explicitly prevents your commitment policy from changing automatically to `require-encrypt-require-decrypt` when you upgrade to version 2.1.x. Instead, you can [migrate your commitment policy \(p. 211\)](#) in stages.

Algorithm suites with key commitment

Version 1.7.x includes two new [algorithm suites \(p. 13\)](#) that support key commitment. One includes signing; the other does not. Like earlier supported algorithm suites, both of these new algorithm suites include encryption with AES-GCM, a 256-bit encryption key, and an HMAC-based extract-and-expand key derivation function (HKDF).

However, the default algorithm suite used for encryption does not change. These algorithm suites are added to version 1.7.x to prepare your application to use them in versions 2.0.x and later.

CMM implementation changes

Version 1.7.x introduces changes to the Default cryptographic materials manager (CMM) interface to support key commitment. This change affects you only if you have written a custom CMM. For details, see the API documentation or GitHub repository for your [programming language \(p. 68\)](#).

Version 1.8.x

Note

All 1.x.x versions of the AWS Encryption SDK are in the [end-of-support phase](#) effective July 2022.

For the AWS Encryption CLI, version 1.8.x is the transition version between versions earlier than 1.7.x and versions 2.1.x and later. For the AWS Encryption CLI, version 1.8.x is fully backward compatible; it does not introduce any breaking changes or change the behavior of the AWS Encryption SDK. It's also forwards compatible; it allows you to update your code so it's compatible with version 2.0.x. It includes new features, but doesn't fully enable them. It requires configuration values that prevent you from immediately adopting all new features until you are ready.

For information about version 1.8.x of the AWS Encryption CLI, see [Version 1.7.x \(p. 195\)](#).

Version 1.9.x

Note

All 1.x.x versions of the AWS Encryption SDK are in the [end-of-support phase](#) effective July 2022.

Version 1.9.x supports the digital signature security improvements found in version 2.2.x. If you currently use digital signatures with your applications and use AWS Encryption SDK versions earlier than version 2.0.x, you should upgrade to version 1.9.x to take advantage of the improvements.

Version 1.9.x also supports limiting the number of encrypted data keys in messages you decrypt from untrusted sources. This best practice feature allows you to detect a misconfigured master key provider or keyring when encrypting messages or a potentially malicious cipher text when decrypting messages.

Like version 1.7.x, version 1.9.x is backwards compatible with versions earlier than 1.7.x and forwards compatible with versions 2.0.x and later. It includes the new features that are present in versions 2.0.x and later, but implements safe defaults. If you're using version 1.9.x, you can safely upgrade to version 2.2.x. For details on how to migrate your commitment policy setting, see [Setting your commitment policy \(p. 211\)](#).

Version 2.0.x

Version 2.0.x supports new security features offered in the AWS Encryption SDK, including specified wrapping keys and key commitment. To support these features, version 2.0.x includes breaking changes for earlier versions of the AWS Encryption SDK. You can prepare for these changes by deploying version 1.7.x. Version 2.0.x includes all of the new features introduced in version 1.7.x with the following additions and changes.

Note

For information about [support and maintenance \(p. 3\)](#) of this AWS Encryption SDK version in your preferred programming language, see the `SUPPORT_POLICY.rs` file in its [GitHub repository \(p. 2\)](#).

AWS KMS master key providers

The original AWS KMS master key provider constructors that were deprecated in version 1.7.x are removed in version 2.0.x. You must explicitly construct AWS KMS master key providers in [strict mode or discovery mode \(p. 204\)](#).

Encrypt and decrypt ciphertext with key commitment

Version 2.0.x can encrypt and decrypt ciphertext with or without [key commitment \(p. 10\)](#). Its behavior is determined by the commitment policy setting. By default, it always encrypts with key commitment and only decrypts ciphertext encrypted with key commitment. Unless you change the commitment policy, the AWS Encryption SDK will not decrypt ciphertexts encrypted by any earlier version of the AWS Encryption SDK, including version 1.7.x.

Important

By default, version 2.0.x will not decrypt any ciphertext that was encrypted without key commitment. If your application might encounter a ciphertext that was encrypted without key commitment, set a commitment policy value with `AllowDecrypt`.

In version 2.0.x, the commitment policy setting has three valid values:

- `ForbidEncryptAllowDecrypt` — The AWS Encryption SDK cannot encrypt with key commitment. It can decrypt ciphertexts encrypted with or without key commitment.
- `RequireEncryptAllowDecrypt` — The AWS Encryption SDK must encrypt with key commitment. It can decrypt ciphertexts encrypted with or without key commitment.
- `RequireEncryptRequireDecrypt` (default) — The AWS Encryption SDK must encrypt with key commitment. It only decrypts ciphertexts with key commitment.

If you are migrating from an earlier version of the AWS Encryption SDK to version 2.0.x, set the commitment policy to a value that assures that you can decrypt all existing ciphertexts that your application might encounter. You are likely to adjust this setting over time.

Version 2.1.x

Note

For information about [support and maintenance \(p. 3\)](#) of this AWS Encryption SDK version in your preferred programming language, see the `SUPPORT_POLICY.rst` file in its [GitHub repository \(p. 2\)](#).

For the AWS Encryption CLI, version 2.1.x is the version that includes specified wrapping keys and key commitment. This is equivalent to version 2.0.x in other programming languages.

For information about version 2.1.x of the AWS Encryption CLI, see [Version 2.0.x \(p. 197\)](#).

Version 2.2.x

Adds support for digital signatures and limiting encrypted data keys.

Note

For information about [support and maintenance \(p. 3\)](#) of this AWS Encryption SDK version in your preferred programming language, see the `SUPPORT_POLICY.rst` file in its [GitHub repository \(p. 2\)](#).

Digital signatures

To improve handling of [digital signatures \(p. 12\)](#) when decrypting, the AWS Encryption SDK includes the following features:

- *Non-streaming mode* — returns plaintext only after processing all input, including verifying the digital signature if present. This feature prevents you from using plaintext before verifying the digital signature. Use this feature whenever you decrypt data encrypted with digital signatures (the default algorithm suite). For example, because the AWS Encryption CLI always processes data in streaming mode, use the `--buffer` parameter when decrypting ciphertext with digital signatures.
- *Unsigned-only decryption mode* — this feature only decrypts unsigned ciphertext. If decryption encounters a digital signature in the ciphertext, the operation fails. Use this feature to avoid unintentionally processing plaintext from signed messages before verifying the signature.

Limiting encrypted data keys

You can [limit the number of encrypted data keys \(p. 41\)](#) in an encrypted message. This feature can help you detect a misconfigured master key provider or keyring when encrypting, or identify a malicious ciphertext when decrypting.

You should limit encrypted data keys when you decrypt messages from an untrusted source. It prevents unnecessary, expensive, and potentially exhaustive calls to your key infrastructure.

Version 2.3.x

Adds support for AWS KMS multi-Region keys. For details, see [Use multi-Region AWS KMS keys \(p. 21\)](#).

Note

The AWS Encryption CLI supports multi-Region keys beginning in [version 3.0.x \(p. 199\)](#). For information about [support and maintenance \(p. 3\)](#) of this AWS Encryption SDK version in your preferred programming language, see the `SUPPORT_POLICY.rst` file in its [GitHub repository \(p. 2\)](#).

Version 2.4.x

The AWS Encryption SDK for Java version 2.4.0 adds support for the AWS SDK for Java 2.x. Beginning in version 2.4.0, the AWS Encryption SDK for Java supports AWS SDK for Java version 1.x and version 2.x. Use of the AWS SDK for Java is optional. The AWS Encryption SDK for Java requires the AWS SDK for Java only if you are using AWS Key Management Service (AWS KMS) as your master key provider.

For details, see [Prerequisites \(p. 85\)](#).

Version 3.0.x

Note

For information about [support and maintenance \(p. 3\)](#) of this AWS Encryption SDK version in your preferred programming language, see the `SUPPORT_POLICY.rst` file in its [GitHub repository \(p. 2\)](#).

AWS Encryption CLI version 3.0.x adds support for AWS KMS multi-Region keys. For details, see in the *AWS Key Management Service Developer Guide*. (Other AWS Encryption SDK programming languages support multi-Region keys beginning in [version 2.3.x \(p. 199\)](#).)

Introduced the AWS Encryption SDK for .NET.

Migrating to AWS Encryption SDK Versions 2.0.x and later

The AWS Encryption SDK supports multiple interoperable [programming language implementations](#) (p. 68), each of which is developed in an open-source repository on GitHub. As a [best practice](#) (p. 17), we recommend that you use the latest version of the AWS Encryption SDK for each language. However, the 2.0.x version of the AWS Encryption SDK introduces significant new security features, some of which are breaking changes. To provide a safe upgrade path from versions earlier than 1.7.x to versions 2.0.x and later, we provide a transition version, 1.7.x, in each programming language. The topics in this section are designed to help you understand the changes, select the correct version for your application, and migrate safely and successfully to the newest versions of the AWS Encryption SDK.

For information about significant versions of the AWS Encryption SDK, see [Versions of the AWS Encryption SDK](#) (p. 194).

Important

Do not upgrade directly from a version earlier than 1.7.x to version 2.0.x or later without first upgrading to version 1.7.x. If you upgrade directly to version 2.0.x or later and enable all new features immediately, the AWS Encryption SDK won't be able to decrypt ciphertext encrypted under older versions of the AWS Encryption SDK.

Note

The earliest version of the AWS Encryption SDK for .NET is version 3.0.x. You do not need to update or migrate to another version if you are using this library.

AWS Encryption CLI: When reading this migration guide, use the 1.7.x migration instructions for AWS Encryption CLI 1.8.x and use the 2.0.x migration instructions for AWS Encryption CLI 2.1.x. For details, see

[We recommend that you use the latest version of the AWS Encryption CLI. If you're using a version of the AWS Encryption CLI older than 2.1.x, we recommend that you upgrade to version 1.8.x and then to version 2.1.x as soon as possible.](#)

[In version 2.1.x, the AWS Encryption CLI introduces support for significant new security features that meet AWS Encryption SDK best practices \(p. 17\). These new features cause breaking changes that will require updates to your commands and scripts. To make migration to version 2.1.x easier, we provide a transition version, 1.8.x that lets you prepare your commands and scripts for 2.1.x. Features that are deprecated in version 1.8.x are removed in version 2.1.x.](#)

Note

[New security features were originally released in AWS Encryption CLI versions 1.7.x and 2.0.x. However, AWS Encryption CLI version 1.8.x replaces version 1.7.x and AWS Encryption CLI 2.1.x replaces 2.0.x. For details, see the relevant security advisory in the aws-encryption-sdk-cli repository on GitHub.](#)

[For information about significant versions of the AWS Encryption SDK, see Versions of the AWS Encryption SDK \(p. 194\).](#)

Which version do I use?

If you're new to the AWS Encryption CLI, use the latest version.

To decrypt data encrypted by a version of the AWS Encryption SDK earlier than version 1.7.x, start with version 1.8.x. Make all recommended changes (p. 203) before updating to version 2.1.x or later. Otherwise, you can begin with the latest available version of the AWS Encryption CLI.

Learn more

- For detailed information about the changes and guidance for migrating to these new versions, see [Migrating to versions 2.0.x and later](#) (p. 200).
- For descriptions of the new AWS Encryption CLI parameters and attributes, see [AWS Encryption SDK CLI syntax and parameter reference](#) (p. 140).

The following lists describe the change to the AWS Encryption CLI in versions 1.8.x and 2.1.x.

Version 1.8.x changes to the AWS Encryption CLI

- Deprecates the `--master-keys` parameter. Instead, use the `--wrapping-keys` parameter.
- Adds the `--wrapping-keys` (`-w`) parameter. It supports all attributes of the `--master-keys` parameter. It also adds the following optional attributes, which are valid only when decrypting with AWS KMS keys.
 - **discovery**
 - **discovery-partition**
 - **discovery-account**For custom master key providers, `--encrypt` and `--decrypt` commands require either a `--wrapping-keys` parameter or a `--master-keys` parameter (but not both). Also, an `--encrypt` command with AWS KMS keys requires either a `--wrapping-keys` parameter or a `--master-keys` parameter (but not both). In a `--decrypt` command with AWS KMS keys, the `--wrapping-keys` parameter is optional, but recommended, because it is required in version 2.1.x. If you use it, you must specify either the **key** attribute or the **discovery** attribute with a value of `true` (but not both).
- Adds the `--commitment-policy` parameter. The only valid value is `forbid-encrypt-allow-decrypt`. The `forbid-encrypt-allow-decrypt` commitment policy is used in all encrypt and decrypt commands. In version 1.8.x, when you use the `--wrapping-keys` parameter, a `--commitment-policy` parameter with the `forbid-encrypt-allow-decrypt` value is required. Setting the value explicitly prevents your commitment policy (p. 11) from changing automatically to `require-encrypt-require-decrypt` when you upgrade to version 2.1.x.

Version 2.1.x changes to the AWS Encryption CLI

- Removes the `--master-keys` parameter. Instead, use the `--wrapping-keys` parameter.

- The `--wrapping-keys` parameter is required in all encrypt and decrypt commands. You must specify either a **key** attribute or a **discovery** attribute with a value of `true` (but not both).
- The `--commitment-policy` parameter supports the following values. For details, see [Setting your commitment policy](#) (p. 211).
 - `forbid-encrypt-allow-decrypt`
 - `require-encrypt-allow-decrypt`
 - `require-encrypt-require-decrypt` (Default)
- The `--commitment-policy` parameter is optional in version 2.1.x. The default value is `require-encrypt-require-decrypt`.

Version 1.9.x and 2.2.x changes to the AWS Encryption CLI

- Adds the `--decrypt-unsigned` parameter. For details, see [Version 2.2.x](#) (p. 198).
- Adds the `--buffer` parameter. For details, see [Version 2.2.x](#) (p. 198).
- Adds the `--max-encrypted-data-keys` parameter. For details, see [Limit encrypted data keys](#) (p. 41).

Version 3.0.x changes to the AWS Encryption CLI

- Adds support for AWS KMS multi-Region keys. For details, see [Use multi-Region AWS KMS keys](#) (p. 21).

(p. 149).

New security features were originally released in AWS Encryption CLI versions 1.7.x and 2.0.x. However, AWS Encryption CLI version 1.8.x replaces version 1.7.x and AWS Encryption CLI 2.1.x replaces 2.0.x. For details, see the relevant [security advisory](#) in the [aws-encryption-sdk-cli](#) repository on GitHub.

New users

If you're new to the AWS Encryption SDK, start with the latest version of the AWS Encryption SDK for your programming language. The default values enable all security features of the AWS Encryption SDK, including encryption with signing, key derivation, and [key commitment](#) (p. 10). of the AWS Encryption SDK

Current users

We recommend that you upgrade from your current version to the newest available version as soon as possible. AWS Encryption SDK versions 2.0.x and later provide new security features to help protect your data.

However, AWS Encryption SDK version 2.0.x includes breaking changes that are not backwards compatible. To assure a safe transition, begin by migrating from your current version to version 1.7.x. When version 1.7.x is fully deployed and operating successfully, you can safely migrate to version 2.0.x. This [two-step process](#) (p. 203) is critical especially for distributed applications.

For more information about the AWS Encryption SDK security features that underlie these changes, see [Improved client-side encryption: Explicit KeyIds and key commitment](#) in the *AWS Security Blog*.

Looking for help with using the AWS Encryption SDK for Java with the AWS SDK for Java 2.x? See [Prerequisites](#) (p. 85).

Topics

- [How to migrate and deploy the AWS Encryption SDK](#) (p. 203)
- [Updating AWS KMS master key providers](#) (p. 204)
- [Updating AWS KMS keyrings](#) (p. 209)
- [Setting your commitment policy](#) (p. 211)
- [Troubleshooting migration to versions 2.0.x and later](#) (p. 217)

How to migrate and deploy the AWS Encryption SDK

When migrating from an AWS Encryption SDK version earlier than 1.7.x to version 2.0.x or later, you must transition safely to encrypting with [key commitment](#) (p. 10). Otherwise, your application will encounter ciphertexts that it cannot decrypt. If you are using AWS KMS master key providers, you must update to new constructors that create master key providers in strict mode or discovery mode.

Note

This topic is designed for users migrating from earlier versions of the AWS Encryption SDK to version 2.0.x or later. If you are new to the AWS Encryption SDK, you can begin using the latest available version immediately with the default settings.

To avoid a critical situation in which you cannot decrypt ciphertext that you need to read, we recommend that you migrate and deploy in multiple distinct stages. Verify that each stage is complete and fully deployed before starting the next stage. This is particularly important for distributed applications with multiple hosts.

Stage 1: Update your application to version 1.7.x

Update to version 1.7.x, test carefully, deploy your changes, and confirm that the update has propagated to all destination hosts before starting stage 2.

Version 1.7.x is backward compatible with legacy versions of the AWS Encryption SDK and forward compatible with version 2.0.x. It includes the new features that are present in version 2.0.x, but it includes safe defaults designed for this migration. It allows you to upgrade your AWS KMS master key providers, if necessary, and to fully deploy with algorithm suites that can decrypt ciphertext with key commitment.

- Replace deprecated elements, including constructors for legacy AWS KMS master key providers. In [Python](#), be sure to turn on deprecation warnings. Code elements that are deprecated in version 1.7.x are removed from version 2.0.x.
- Explicitly set your commitment policy to `ForbidEncryptAllowDecrypt`. Although this is the only valid value in version 1.7.x, this setting is required when you use the APIs introduced in this release. It prevents your application from rejecting ciphertext encrypted without key commitment when you migrate to version 2.0.x. For details, see [the section called “Setting your commitment policy”](#) (p. 211).
- If you use AWS KMS master key providers, you must update your legacy master key providers to master key providers that support *strict mode* and *discovery mode*. This update is required for the AWS Encryption SDK for Java, AWS Encryption SDK for Python, and the AWS Encryption CLI. If you use master key providers in discovery mode, we recommend that you implement the new filter that limits the wrapping keys used to those in particular AWS accounts. This update is optional, but it's a [best practice](#) (p. 17) that we recommend. For details, see [Updating AWS KMS master key providers](#) (p. 204).

- If you use [AWS KMS discovery keyrings \(p. 55\)](#) in the AWS Encryption SDK for C and AWS Encryption SDK for JavaScript, we recommend that you implement the new filter that limits the wrapping keys used to those in particular AWS accounts. This update is optional, but it's a [best practice \(p. 17\)](#) that we recommend. For details, see [Updating AWS KMS keyrings \(p. 209\)](#).

Stage 2: Update your application to version 2.0.x

After deploying version 1.7.x successfully to all hosts, you can upgrade to version 2.0.x. Version 2.0.x includes breaking changes for all earlier versions of the AWS Encryption SDK. However, if you make the code changes recommended in Stage 1, you can avoid errors when you migrate to version 2.0.x.

When you update to versions 2.0.x and later from 1.7.x, verify that your commitment policy is consistently set to `ForbidEncryptAllowDecrypt`. Then, depending on your data configuration, you can migrate at your own pace to `RequireEncryptAllowDecrypt` and then to the default setting, `RequireEncryptRequireDecrypt`. We recommend a series of transition steps like the following pattern.

1. Begin with your [commitment policy \(p. 211\)](#) set to `ForbidEncryptAllowDecrypt`. The AWS Encryption SDK can decrypt messages with key commitment, but it doesn't yet encrypt with key commitment.
2. When you are ready, you can update your commitment policy to `RequireEncryptAllowDecrypt`. The AWS Encryption SDK begins to encrypt your data with [key commitment \(p. 10\)](#). It can decrypt ciphertext with and without key commitment.

Before updating your commitment policy to `RequireEncryptAllowDecrypt`, verify that version 1.7.x is deployed to all hosts, including hosts of any applications that decrypt the ciphertext you produce. Versions of the AWS Encryption SDK prior to version 1.7.x cannot decrypt messages encrypted with key commitment.

This is also a good time to add metrics to your application to measure whether you are still processing ciphertext without key commitment. This will help you determine when it's safe to update your commitment policy setting to `RequireEncryptRequireDecrypt`. For some applications, such as those that encrypt messages in an Amazon SQS queue, this might mean waiting long enough that all ciphertext encrypted under old versions have been re-encrypted or deleted. For other applications, such as encrypted S3 objects, you might need to download, re-encrypt, and re-upload all objects.

3. When you are certain that you don't have any messages encrypted without key commitment, you can update your commitment policy to `RequireEncryptRequireDecrypt`. This value assures that your data is always encrypted and decrypted with key commitment. This setting is the default, so you aren't required to set it explicitly, but we recommend it. An explicit setting will [aid debugging \(p. 217\)](#) and any potential rollbacks that might be required if your application encounters ciphertext encrypted without key commitment.

Updating AWS KMS master key providers

To migrate to versions 1.7.x and then to version 2.0.x or later, you must replace legacy AWS KMS master key providers with master key providers created explicitly in [strict mode or discovery mode \(p. 195\)](#). Legacy master key providers are deprecated in version 1.7.x and removed in version 2.0.x. This change is required for applications and scripts that use the [AWS Encryption SDK for Java \(p. 85\)](#), [AWS Encryption SDK for Python \(p. 103\)](#), and the [AWS Encryption CLI \(p. 112\)](#). The examples in this section will show you how to update your code.

Note

In Python, [turn on deprecation warnings](#). This will help you identify the parts of your code that you need to update.

If you are using an AWS KMS master key (not a master key provider), you can skip this step. AWS KMS master keys are not deprecated or removed. They encrypt and decrypt only with the wrapping keys that you specify.

The examples in this section focus on the elements of your code that you need to change. For a complete example of the updated code, see the Examples section of the GitHub repository for your [programming language](#) (p. 68). Also, these examples typically use key ARNs to represent AWS KMS keys. When you create a master key provider for encrypting, you can use any valid AWS KMS [key identifier](#) to represent an AWS KMS key. When you create a master key provider for decrypting, you must use a key ARN.

Learn more about migration

For all AWS Encryption SDK users, learn about setting your commitment policy in [the section called "Setting your commitment policy"](#) (p. 211).

For AWS Encryption SDK for C and AWS Encryption SDK for JavaScript users, learn about an optional update to keyrings in [Updating AWS KMS keyrings](#) (p. 209).

Topics

- [Migrating to strict mode](#) (p. 205)
- [Migrating to discovery mode](#) (p. 207)

Migrating to strict mode

After updating to version 1.7.x, you can replace your legacy master key providers with master key providers in strict mode. In strict mode, you must specify the wrapping keys to use when encrypting and decrypting. The AWS Encryption SDK uses only the wrapping keys you specify. Deprecated master key providers can decrypt data using any AWS KMS key that encrypted a data key, including AWS KMS keys in different AWS accounts and Regions.

Master key providers in strict mode are introduced in the AWS Encryption SDK version 1.7.x. They replace legacy master key providers, which are deprecated in 1.7.x and removed in 2.0.x. Using master key providers in strict mode is an AWS Encryption SDK [best practice](#) (p. 17).

The following code creates a master key provider in strict mode that you can use for encrypting and decrypting.

Java

This example represents code in an application that uses the version 1.6.2 or earlier of the AWS Encryption SDK for Java.

This code uses the `KmsMasterKeyProvider.builder()` method to instantiate an AWS KMS master key provider that uses one AWS KMS key as a wrapping key.

```
// Create a master key provider
// Replace the example key ARN with a valid one
String awsKmsKey = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

KmsMasterKeyProvider masterKeyProvider = KmsMasterKeyProvider.builder()
    .withKeysForEncryption(awsKmsKey)
    .build();
```

This example represents code in an application that uses version 1.7.x or later of the AWS Encryption SDK for Java. For a complete example, see [BasicEncryptionExample.java](#).

The `Builder.build()` and `Builder.withKeysForEncryption()` methods used in the previous example are deprecated in version 1.7.x and are removed from version 2.0.x.

To update to a strict mode master key provider, this code replaces calls to deprecated methods with a call to the new `Builder.buildStrict()` method. This example specifies one AWS KMS key as the wrapping key, but the `Builder.buildStrict()` method can take a list of multiple AWS KMS keys.

```
// Create a master key provider in strict mode
// Replace the example key ARN with a valid one from your AWS account.
String awsKmsKey = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

KmsMasterKeyProvider masterKeyProvider = KmsMasterKeyProvider.builder()
    .buildStrict(awsKmsKey);
```

Python

This example represents code in an application that uses version 1.4.1 of the AWS Encryption SDK for Python. This code uses `KMSMasterKeyProvider`, which is deprecated in version 1.7.x and removed from version 2.0.x. When decrypting, it uses any AWS KMS key that encrypted a data key without regard to the AWS KMS keys you specify.

Note that `KMSMasterKey` is not deprecated or removed. When encrypting and decrypting, it uses only the AWS KMS key you specify.

```
# Create a master key provider
# Replace the example key ARN with a valid one
key_1 = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
key_2 = "arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321"

aws_kms_master_key_provider = KMSMasterKeyProvider(
    key_ids=[key_1, key_2]
)
```

This example represents code in an application that uses version 1.7.x of the AWS Encryption SDK for Python. For a complete example, see [basic_encryption.py](#).

To update to a strict mode master key provider, this code replaces the call to `KMSMasterKeyProvider()` with a call to `StrictAwsKmsMasterKeyProvider()`.

```
# Create a master key provider in strict mode
# Replace the example key ARNs with valid values from your AWS account
key_1 = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
key_2 = "arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321"

aws_kms_master_key_provider = StrictAwsKmsMasterKeyProvider(
    key_ids=[key_1, key_2]
)
```

AWS Encryption CLI

This example shows how to encrypt and decrypt using the AWS Encryption CLI version 1.1.7 or earlier.

In version 1.1.7 and earlier, when encrypting, you specify one or more master keys (or *wrapping keys*), such as an AWS KMS key. When decrypting, you can't specify any wrapping keys unless you are using a custom master key provider. The AWS Encryption CLI can use any wrapping key that encrypted a data key.

```
\\ Replace the example key ARN with a valid one
$ keyArn=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab
```

```
\\ Encrypt your plaintext data
$ aws-encryption-cli --encrypt \
    --input hello.txt \
    --master-keys key=$keyArn \
    --metadata-output ~/metadata \
    --encryption-context purpose=test \
    --output .

\\ Decrypt your ciphertext
$ aws-encryption-cli --decrypt \
    --input hello.txt.encrypted \
    --encryption-context purpose=test \
    --metadata-output ~/metadata \
    --output .
```

This example shows how to encrypt and decrypt using the AWS Encryption CLI version 1.7.x or later. For complete examples, see [Examples of the AWS Encryption CLI \(p. 124\)](#).

The `--master-keys` parameter is deprecated in version 1.7.x and removed in version 2.0.x. It's replaced by the `--wrapping-keys` parameter, which is required in encrypt and decrypt commands. This parameter supports strict mode and discovery mode. Strict mode is an AWS Encryption SDK best practice that assures that you use the wrapping key that you intend.

To upgrade to *strict mode*, use the **key** attribute of the `--wrapping-keys` parameter to specify a wrapping key when encrypting and decrypting.

```
\\ Replace the example key ARN with a valid value
$ keyArn=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab

\\ Encrypt your plaintext data
$ aws-encryption-cli --encrypt \
    --input hello.txt \
    --wrapping-keys key=$keyArn \
    --metadata-output ~/metadata \
    --encryption-context purpose=test \
    --output .

\\ Decrypt your ciphertext
$ aws-encryption-cli --decrypt \
    --input hello.txt.encrypted \
    --wrapping-keys key=$keyArn \
    --encryption-context purpose=test \
    --metadata-output ~/metadata \
    --output .
```

Migrating to discovery mode

Beginning in version 1.7.x, it's an AWS Encryption SDK [best practice \(p. 17\)](#) to use *strict mode* for AWS KMS master key providers, that is, to specify wrapping keys when encrypting and decrypting. You must always specify wrapping keys when encrypting. But there are situations in which specifying the key ARNs of AWS KMS keys for decrypting is impractical. For example, if you're using aliases to identify AWS KMS keys when encrypting, you lose the benefit of aliases if you have to list key ARNs when decrypting. Also, because master key providers in discovery mode behave like the original master key providers, you might use them temporarily as part of your migration strategy, and then upgrade to master key providers in strict mode later.

In cases like this, you can use master key providers in *discovery mode*. These master key providers don't let you specify wrapping keys, so you cannot use them for encrypting. When decrypting, they can use any wrapping key that encrypted a data key. But unlike legacy master key providers, which behave the

same way, you create them in discovery mode explicitly. When using master key providers in discovery mode, you can limit the wrapping keys that can be used to those in particular AWS accounts. This filter is optional, but it's a best practice that we recommend. For information about AWS partitions and accounts, see [Amazon Resource Names](#) in the *AWS General Reference*.

The following examples create an AWS KMS master key provider in strict mode for encrypting and an AWS KMS master key provider in discovery mode for decrypting. The master key provider in discovery mode uses a discovery filter to limit the wrapping keys used for decrypting to the aws partition and to particular example AWS accounts. Although the account filter is not necessary in this very simple example, it's a best practice that is very beneficial when one application encrypts data and a different application decrypts the data.

Java

This example represents code in an application that uses version 1.7.x or later of the AWS Encryption SDK for Java. For a complete example, see [DiscoveryDecryptionExample.java](#).

To instantiate a master key provider in strict mode for encrypting, this example uses the `Builder.buildStrict()` method. To instantiate a master key provider in discovery mode for decrypting, it uses the `Builder.buildDiscovery()` method. The `Builder.buildDiscovery()` method takes a `DiscoveryFilter` that limits the AWS Encryption SDK to AWS KMS keys in the specified AWS partition and accounts.

```
// Create a master key provider in strict mode for encrypting
// Replace the example alias ARN with a valid one from your AWS account.
String awsKmsKey = "arn:aws:kms:us-west-2:111122223333:alias/ExampleAlias";

KmsMasterKeyProvider encryptingKeyProvider = KmsMasterKeyProvider.builder()
    .buildStrict(awsKmsKey);

// Create a master key provider in discovery mode for decrypting
// Replace the example account IDs with valid values.
DiscoveryFilter accounts = new DiscoveryFilter("aws", Arrays.asList("111122223333",
    "444455556666"));

KmsMasterKeyProvider decryptingKeyProvider = KmsMasterKeyProvider.builder()
    .buildDiscovery(accounts);
```

Python

This example represents code in an application that uses version 1.7.x or later of the AWS Encryption SDK for Python. For a complete example, see [discovery_kms_provider.py](#).

To create a master key provider in strict mode for encrypting, this example uses `StrictAwsKmsMasterKeyProvider`. To create a master key provider in discovery mode for decrypting, it uses `DiscoveryAwsKmsMasterKeyProvider` with a `DiscoveryFilter` that limits the AWS Encryption SDK to AWS KMS keys in the specified AWS partition and accounts.

```
# Create a master key provider in strict mode
# Replace the example key ARN and alias ARNs with valid values from your AWS account.
key_1 = "arn:aws:kms:us-west-2:111122223333:alias/ExampleAlias"
key_2 = "arn:aws:kms:us-west-2:444455556666:key/1a2b3c4d-5e6f-1a2b-3c4d-5e6f1a2b3c4d"

aws_kms_master_key_provider = StrictAwsKmsMasterKeyProvider(
    key_ids=[key_1, key_2]
)

# Create a master key provider in discovery mode for decrypting
# Replace the example account IDs with valid values
accounts = DiscoveryFilter(
    partition="aws",
```

```
        account_ids=["111122223333", "444455556666"]
    )
    aws_kms_master_key_provider = DiscoveryAwsKmsMasterKeyProvider(
        discovery_filter=accounts
    )
```

AWS Encryption CLI

This example shows how to encrypt and decrypt using the AWS Encryption CLI version 1.7.x or later. Beginning in version 1.7.x, the `--wrapping-keys` parameter is required when encrypting and decrypting. The `--wrapping-keys` parameter supports strict mode and discovery mode. For complete examples, see [the section called “Examples” \(p. 124\)](#).

When encrypting, this example specifies a wrapping key, which is required. When decrypting, it explicitly chooses *discovery mode* by using the `discovery` attribute of the `--wrapping-keys` parameter with a value of `true`.

To limit the wrapping keys that the AWS Encryption SDK can use in discovery mode to those in particular AWS accounts, this example uses the `discovery-partition` and `discovery-account` attributes of the `--wrapping-keys` parameter. These optional attributes are valid only when the `discovery` attribute is set to `true`. You must use the `discovery-partition` and `discovery-account` attributes together; neither is valid alone.

```
\\ Replace the example key ARN with a valid value
$ keyAlias=arn:aws:kms:us-west-2:111122223333:alias/ExampleAlias

\\ Encrypt your plaintext data
$ aws-encryption-cli --encrypt \
    --input hello.txt \
    --wrapping-keys key=$keyAlias \
    --metadata-output ~/metadata \
    --encryption-context purpose=test \
    --output .

\\ Decrypt your ciphertext
\\ Replace the example account IDs with valid values
$ aws-encryption-cli --decrypt \
    --input hello.txt.encrypted \
    --wrapping-keys discovery=true \
    discovery-partition=aws \
    discovery-account=111122223333 \
    discovery-account=444455556666 \
    --encryption-context purpose=test \
    --metadata-output ~/metadata \
    --output .
```

Updating AWS KMS keyrings

The AWS KMS keyrings in the [AWS Encryption SDK for C \(p. 68\)](#), the [AWS Encryption SDK for .NET \(p. 77\)](#), and the [AWS Encryption SDK for JavaScript \(p. 95\)](#) support [best practices \(p. 17\)](#) by allowing you to specify wrapping keys when encrypting and decrypting. If you create an [AWS KMS discovery keyring \(p. 55\)](#), you do so explicitly.

Note

The earliest version of the AWS Encryption SDK for .NET is version 3.0.x. You do not need to update or migrate to another version if you are using this library.

When you update to versions 1.7.x and later, you can also limit the wrapping keys that any [AWS KMS discovery keyring \(p. 55\)](#) or [AWS KMS regional discovery keyring \(p. 56\)](#) uses when decrypting to those in particular AWS accounts. Filtering a discovery keyring is an AWS Encryption SDK [best practice \(p. 17\)](#).

The examples in this section will show you how to add the discovery filter to an AWS KMS regional discovery keyring.

Learn more about migration

For all AWS Encryption SDK users, learn about setting your commitment policy in [the section called “Setting your commitment policy” \(p. 211\)](#).

For AWS Encryption SDK for Java, AWS Encryption SDK for Python, and AWS Encryption CLI users, learn about a required update to master key providers in [the section called “Updating AWS KMS master key providers” \(p. 204\)](#).

You might have code like the following in your application. This example creates an AWS KMS regional discovery keyring that can only use wrapping keys in the US West (Oregon) (us-west-2) Region. This example represents code in AWS Encryption SDK versions earlier than 1.7.x. However, it is still valid in versions 1.7.x and later.

C

```
struct aws_cryptosdk_keyring *kms_regional_keyring =  
    Aws::Cryptosdk::KmsKeyring::Builder()  
        .WithKmsClient(create_kms_client(Aws::Region::US_WEST_2)).BuildDiscovery();
```

JavaScript Browser

```
const clientProvider = getClient(KMS, { credentials })  
  
const discovery = true  
const clientProvider = limitRegions(['us-west-2'], getKmsClient)  
const keyring = new KmsKeyringBrowser({ clientProvider, discovery })
```

JavaScript Node.js

```
const discovery = true  
const clientProvider = limitRegions(['us-west-2'], getKmsClient)  
const keyring = new KmsKeyringNode({ clientProvider, discovery })
```

Beginning in version 1.7.x, you can add a discovery filter to any AWS KMS discovery keyring. This discovery filter limits the AWS KMS keys that the AWS Encryption SDK can use for decryption to those in the specified partition and accounts. Before using this code, change the partition, if necessary, and replace the example account IDs with valid ones.

C

For a complete example, see [kms_discovery.cpp](#).

```
std::shared_ptr<KmsKeyring::DiscoveryFilter> discovery_filter(  
    KmsKeyring::DiscoveryFilter::Builder("aws")  
        .AddAccount("111122223333")  
        .AddAccount("444455556666")  
        .Build());  
  
struct aws_cryptosdk_keyring *kms_regional_keyring =  
    Aws::Cryptosdk::KmsKeyring::Builder()  
        .WithKmsClient(create_kms_client(Aws::Region::US_WEST_2)).BuildDiscovery(discovery_filter);
```

JavaScript Browser

```
const clientProvider = getClient(KMS, { credentials })

const discovery = true
const clientProvider = limitRegions(['us-west-2'], getKmsClient)
const keyring = new KmsKeyringBrowser(clientProvider, {
  discovery,
  discoveryFilter: { accountIDs: ['111122223333', '444455556666'], partition: 'aws' }
})
```

JavaScript Node.js

For a complete example, see [kms_filtered_discovery.ts](#).

```
const discovery = true
const clientProvider = limitRegions(['us-west-2'], getKmsClient)
const keyring = new KmsKeyringNode({
  clientProvider,
  discovery,
  discoveryFilter: { accountIDs: ['111122223333', '444455556666'], partition: 'aws' }
})
```

Setting your commitment policy

[Key commitment \(p. 10\)](#) assures that your encrypted data always decrypts to the same plaintext. To provide this security property, beginning in version 1.7.x, the AWS Encryption SDK uses new [algorithm suites \(p. 13\)](#) with key commitment. To determine whether your data is encrypted and decrypted with key commitment, use the [commitment policy \(p. 11\)](#) configuration setting. Encrypting and decrypting data with key commitment is an [AWS Encryption SDK best practice \(p. 17\)](#).

Setting a commitment policy is an important step in migrating from version 1.7.x of the AWS Encryption SDK to versions 2.0.x and later. After setting and changing your commitment policy, be sure to test your application thoroughly before deploying it in production. For migration guidance, see [How to migrate and deploy the AWS Encryption SDK \(p. 203\)](#).

The commitment policy setting has three valid values in versions 2.0.x and later. In version 1.7.x, only `ForbidEncryptAllowDecrypt` is valid.

- `ForbidEncryptAllowDecrypt` — The AWS Encryption SDK cannot encrypt with key commitment. It can decrypt ciphertexts encrypted with or without key commitment.

In version 1.7.x, this is the only valid value. It ensures that you don't encrypt with key commitment until you are fully prepared to decrypt with key commitment. Setting the value explicitly prevents your commitment policy from changing automatically to `require-encrypt-require-decrypt` when you upgrade to version 2.0.x or later. Instead, you can [migrate your commitment policy \(p. 211\)](#) in stages.

- `RequireEncryptAllowDecrypt` — The AWS Encryption SDK must encrypt with key commitment. It can decrypt ciphertexts encrypted with or without key commitment. This value is added in version 2.0.x.
- `RequireEncryptRequireDecrypt` — The AWS Encryption SDK must encrypt with key commitment. It only decrypts ciphertexts with key commitment. This value is added in version 2.0.x. It is the default value in versions 2.0.x and later.

In version 1.7.x, the only valid commitment policy value is `ForbidEncryptAllowDecrypt`. After you migrate to version 2.0.x or later, you can [change your commitment policy in stages \(p. 203\)](#) as you

are ready. Don't update your commitment policy to `RequireEncryptRequireDecrypt` until you are certain that you don't have any messages encrypted without key commitment.

These examples show you how to set your commitment policy in versions 1.7.x and 2.0.x and later. The technique depends on your programming language.

Learn more about migration

For AWS Encryption SDK for Java, AWS Encryption SDK for Python, and the AWS Encryption CLI, learn about required changes to master key providers in [the section called "Updating AWS KMS master key providers" \(p. 204\)](#).

For AWS Encryption SDK for C and AWS Encryption SDK for JavaScript, learn about an optional update to keyrings in [Updating AWS KMS keyrings \(p. 209\)](#).

How to set your commitment policy

The technique that you use to set your commitment policy differs slightly with each language implementation. These examples show you how to do it. Before changing your commitment policy, review the multi-stage approach in [How to migrate and deploy \(p. 203\)](#).

C

Beginning in version 1.7.x of the AWS Encryption SDK for C, you use the `aws_cryptosdk_session_set_commitment_policy` function to set the commitment policy on your encrypt and decrypt sessions. The commitment policy that you set applies to all encrypt and decrypt operations called on that session.

The `aws_cryptosdk_session_new_from_keyring` and `aws_cryptosdk_session_new_from_cmm` functions are deprecated in version 1.7.x and removed in version 2.0.x. These functions are replaced by `aws_cryptosdk_session_new_from_keyring_2` and `aws_cryptosdk_session_new_from_cmm_2` functions that return a session.

When you use the `aws_cryptosdk_session_new_from_keyring_2` and `aws_cryptosdk_session_new_from_cmm_2` in version 1.7.x, you are required to call the `aws_cryptosdk_session_set_commitment_policy` function with the `COMMITMENT_POLICY_FORBID_ENCRYPT_ALLOW_DECRYPT` commitment policy value. In version 2.0.x, calling this function is optional and it takes all valid values. The default commitment policy for versions 2.0.x and later is `COMMITMENT_POLICY_REQUIRE_ENCRYPT_REQUIRE_DECRYPT`.

For a complete example, see [string.cpp](#).

```
/* Load error strings for debugging */
aws_cryptosdk_load_error_strings();

/* Create an AWS KMS keyring */
const char * key_arn = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
struct aws_cryptosdk_keyring *kms_keyring =  
    Aws::Cryptosdk::KmsKeyring::Builder().Build(key_arn);

/* Create an encrypt session with a CommitmentPolicy setting */
struct aws_cryptosdk_session *encrypt_session =  
    aws_cryptosdk_session_new_from_keyring_2(  
        alloc, AWS_CRYPTOSDK_ENCRYPT, kms_keyring);

aws_cryptosdk_keyring_release(kms_keyring);
aws_cryptosdk_session_set_commitment_policy(encrypt_session,  
    COMMITMENT_POLICY_FORBID_ENCRYPT_ALLOW_DECRYPT);
```

```
...
/* Encrypt your data */

size_t plaintext_consumed_output;
aws_cryptosdk_session_process(encrypt_session,
                              ciphertext_output,
                              ciphertext_buf_sz_output,
                              ciphertext_len_output,
                              plaintext_input,
                              plaintext_len_input,
                              &plaintext_consumed_output)
...

/* Create a decrypt session with a CommitmentPolicy setting */

struct aws_cryptosdk_keyring *kms_keyring =
    Aws::Cryptosdk::KmsKeyring::Builder().Build(key_arn);
struct aws_cryptosdk_session *decrypt_session =
    *aws_cryptosdk_session_new_from_keyring_2(
        alloc, AWS_CRYPTOSDK_DECRYPT, kms_keyring);
aws_cryptosdk_keyring_release(kms_keyring);
aws_cryptosdk_session_set_commitment_policy(decrypt_session,
    COMMITMENT_POLICY_FORBID_ENCRYPT_ALLOW_DECRYPT);

/* Decrypt your ciphertext */
size_t ciphertext_consumed_output;
aws_cryptosdk_session_process(decrypt_session,
                              plaintext_output,
                              plaintext_buf_sz_output,
                              plaintext_len_output,
                              ciphertext_input,
                              ciphertext_len_input,
                              &ciphertext_consumed_output)
```

C# / .NET

The `require-encrypt-require-decrypt` value is the default commitment policy in all versions of the AWS Encryption SDK for .NET. You can set it explicitly as a best practice, but it's not required. However, if you are using the AWS Encryption SDK for .NET to decrypt ciphertext that was encrypted by another language implementation of the AWS Encryption SDK without key commitment, you need to change the commitment policy value to `REQUIRE_ENCRYPT_ALLOW_DECRYPT` or `FORBID_ENCRYPT_ALLOW_DECRYPT`. Otherwise, attempts to decrypt the ciphertext will fail.

In the AWS Encryption SDK for .NET, you set the commitment policy on an instance of the AWS Encryption SDK. Instantiate an `AwsEncryptionSdkConfig` object with a `CommitmentPolicy` parameter, and use the configuration object to create the AWS Encryption SDK instance. Then, call the `Encrypt()` and `Decrypt()` methods of the configured AWS Encryption SDK instance.

This example sets the commitment policy to `require-encrypt-allow-decrypt`.

```
// Instantiate the material providers
var materialProviders =

    AwsCryptographicMaterialProvidersFactory.CreateDefaultAwsCryptographicMaterialProviders();

// Configure the commitment policy on the AWS Encryption SDK instance
var config = new AwsEncryptionSdkConfig
{
    CommitmentPolicy = CommitmentPolicy.REQUIRE_ENCRYPT_ALLOW_DECRYPT
};
var encryptionSdk = AwsEncryptionSdkFactory.CreateAwsEncryptionSdk(config);

string keyArn = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
```

```
var encryptionContext = new Dictionary<string, string>()
{
    {"purpose", "test"}encryptionSdk
};

var createKeyringInput = new CreateAwsKmsKeyringInput
{
    KmsClient = new AmazonKeyManagementServiceClient(),
    KmsKeyId = keyArn
};
var keyring = materialProviders.CreateAwsKmsKeyring(createKeyringInput);

// Encrypt your plaintext data
var encryptInput = new EncryptInput
{
    Plaintext = plaintext,
    Keyring = keyring,
    EncryptionContext = encryptionContext
};
var encryptOutput = encryptionSdk.Encrypt(encryptInput);

// Decrypt your ciphertext
var decryptInput = new DecryptInput
{
    Ciphertext = ciphertext,
    Keyring = keyring
};
var decryptOutput = encryptionSdk.Decrypt(decryptInput);
```

AWS Encryption CLI

To set a commitment policy in the AWS Encryption CLI, use the `--commitment-policy` parameter. This parameter is introduced in version 1.8.x.

In version 1.8.x, when you use the `--wrapping-keys` parameter in an `--encrypt` or `--decrypt` command, a `--commitment-policy` parameter with the `forbid-encrypt-allow-decrypt` value is required. Otherwise, the `--commitment-policy` parameter is invalid.

In versions 2.1.x and later, the `--commitment-policy` parameter is optional and defaults to the `require-encrypt-require-decrypt` value, which won't encrypt or decrypt any ciphertext encrypted without key commitment. However, we recommend that you set the commitment policy explicitly in all encrypt and decrypt calls to help with maintenance and troubleshooting.

This example sets the commitment policy. It also uses the `--wrapping-keys` parameter that replaces the `--master-keys` parameter beginning in version 1.8.x. For details, see [the section called "Updating AWS KMS master key providers" \(p. 204\)](#). For complete examples, see [Examples of the AWS Encryption CLI \(p. 124\)](#).

```
\\ To run this example, replace the fictitious key ARN with a valid value.
$ keyArn=arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab

\\ Encrypt your plaintext data - no change to algorithm suite used
$ aws-encryption-cli --encrypt \
    --input hello.txt \
    --wrapping-keys key=$keyArn \
    --commitment-policy forbid-encrypt-allow-decrypt \
    --metadata-output ~/metadata \
    --encryption-context purpose=test \
    --output .

\\ Decrypt your ciphertext - supports key commitment on 1.7 and later
$ aws-encryption-cli --decrypt \
```

```
--input hello.txt.encrypted \  
--wrapping-keys key=$keyArn \  
--commitment-policy forbid-encrypt-allow-decrypt \  
--encryption-context purpose=test \  
--metadata-output ~/metadata \  
--output .
```

Java

Beginning in version 1.7.x of the AWS Encryption SDK for Java, you set the commitment policy on your instance of `AwsCrypto`, the object that represents the AWS Encryption SDK client. This commitment policy setting applies to all encrypt and decrypt operations called on that client.

The `AwsCrypto()` constructor is deprecated in 1.7.x and removed in 2.0.x. It's replaced by a new `Builder` class, a `Builder.withCommitmentPolicy()` method, and the `CommitmentPolicy` enumerated type.

In version 1.7.x, the `Builder` class requires the `Builder.withCommitmentPolicy()` method and the `CommitmentPolicy.ForbidEncryptAllowDecrypt` argument. Beginning in version 2.0.x, the `Builder.withCommitmentPolicy()` method is optional; the default value is `CommitmentPolicy.RequireEncryptRequireDecrypt`.

For a complete example, see [SetCommitmentPolicyExample.java](#).

```
// Instantiate the client  
final AwsCrypto crypto = AwsCrypto.builder()  
    .withCommitmentPolicy(CommitmentPolicy.ForbidEncryptAllowDecrypt)  
    .build();  
  
// Create a master key provider in strict mode \(p. 205\)  
String awsKmsKey = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
KmsMasterKeyProvider masterKeyProvider = KmsMasterKeyProvider.builder()  
    .buildStrict(awsKmsKey);  
  
// Encrypt your plaintext data  
CryptoResult<byte[], KmsMasterKey> encryptResult = crypto.encryptData(  
    masterKeyProvider,  
    sourcePlaintext,  
    encryptionContext);  
byte[] ciphertext = encryptResult.getResult();  
  
// Decrypt your ciphertext  
CryptoResult<byte[], KmsMasterKey> decryptResult = crypto.decryptData(  
    masterKeyProvider,  
    ciphertext);  
byte[] decrypted = decryptResult.getResult();
```

JavaScript

Beginning in version 1.7.x of the AWS Encryption SDK for JavaScript, you can set the commitment policy when you call the new `buildClient` function that instantiates an AWS Encryption SDK client. The `buildClient` function takes an enumerated value that represents your commitment policy. It returns updated `encrypt` and `decrypt` functions that enforce your commitment policy when you encrypt and decrypt.

In version 1.7.x, the `buildClient` function requires the `CommitmentPolicy.FORBID_ENCRYPT_ALLOW_DECRYPT` argument. Beginning in version 2.0.x, the commitment policy argument is optional and the default value is `CommitmentPolicy.REQUIRE_ENCRYPT_REQUIRE_DECRYPT`.

The code for Node.js and the browser are identical for this purpose, except that browser needs a statement to set credentials.

The following example encrypts data with an AWS KMS keyring. The new `buildClient` function sets the commitment policy to the 1.7.x default value. The upgraded `encrypt` and `decrypt` functions that `buildClient` returns enforce the commitment policy you set.

```
import { buildClient } from '@aws-crypto/client-node'
const { encrypt, decrypt } = buildClient(CommitmentPolicy.FORBID_ENCRYPT_ALLOW_DECRYPT)

// Create an AWS KMS keyring
const generatorKeyId = 'arn:aws:kms:us-west-2:111122223333:alias/ExampleAlias'
const keyIds = ['arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab']
const keyring = new KmsKeyringNode({ generatorKeyId, keyIds })

// Encrypt your plaintext data
const { ciphertext } = await encrypt(keyring, plaintext, { encryptionContext:
  context })

// Decrypt your ciphertext
const { decrypted, messageHeader } = await decrypt(keyring, ciphertext)
```

Python

Beginning in version 1.7.x of the AWS Encryption SDK for Python, you set the commitment policy on your instance of `EncryptionSDKClient`, a new object that represents the AWS Encryption SDK client. The commitment policy that you set applies to all `encrypt` and `decrypt` calls that use that instance of the client.

In version 1.7.x, the `EncryptionSDKClient` constructor requires the `CommitmentPolicy.ForbidEncryptAllowDecrypt` enumerated value. Beginning in version 2.0.x, the commitment policy argument is optional and the default value is `CommitmentPolicy.RequireEncryptRequireDecrypt`.

This example uses the new `EncryptionSDKClient` constructor and sets the commitment policy to the 1.7.x default value. The constructor instantiates a client that represents the AWS Encryption SDK. When you call the `encrypt`, `decrypt`, or `stream` methods on this client, they enforce the commitment policy that you set. This example also uses the new constructor for the `StrictAwsKmsMasterKeyProvider` class, which specifies AWS KMS keys when encrypting and decrypting.

For a complete example, see [set_commitment.py](#).

```
# Instantiate the client
client = EncryptionSDKClient(CommitmentPolicy.ForbidEncryptAllowDecrypt)

// Create a master key provider in strict mode (p. 205)
aws_kms_key = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
aws_kms_strict_master_key_provider = StrictAwsKmsMasterKeyProvider(
    key_ids=[aws_kms_key]
)

# Encrypt your plaintext data
ciphertext, encrypt_header = client.encrypt(
    source=source_plaintext,
    encryption_context=encryption_context,
    master_key_provider=aws_kms_strict_master_key_provider
)
```

```
# Decrypt your ciphertext
decrypted, decrypt_header = client.decrypt(
    source=ciphertext,
    master_key_provider=aws_kms_strict_master_key_provider
)
```

Troubleshooting migration to versions 2.0.x and later

Before updating your application to version 2.0.x or later of the AWS Encryption SDK, update to version 1.7.x and deploy it completely. That will help you avoid most errors you might encounter when updating to version 2.0.x. For detailed guidance, including examples, see [Migrating to versions 2.0.x and later](#) (p. 200).

Note

AWS Encryption CLI: References in this guide to version 1.7.x of the AWS Encryption SDK apply to version 1.8.x of the AWS Encryption CLI. References in this guide to version 2.0.x of the AWS Encryption SDK apply to 2.1.x of the AWS Encryption CLI.

New security features were originally released in AWS Encryption CLI versions 1.7.x and 2.0.x. However, AWS Encryption CLI version 1.8.x replaces version 1.7.x and AWS Encryption CLI 2.1.x replaces 2.0.x. For details, see the relevant [security advisory](#) in the [aws-encryption-sdk-cli](#) repository on GitHub.

This topic is designed to help you recognize and resolve the most common errors you might encounter.

Topics

- [Deprecated or removed objects](#) (p. 217)
- [Configuration conflict: Commitment policy and algorithm suite](#) (p. 217)
- [Configuration conflict: Commitment policy and ciphertext](#) (p. 218)
- [Key commitment validation failed](#) (p. 218)
- [Other encryption failures](#) (p. 219)
- [Other decryption failures](#) (p. 219)
- [Rollback considerations](#) (p. 219)

Deprecated or removed objects

Version 2.0.x includes several breaking changes, including removing legacy constructors, methods, functions, and classes that were deprecated in version 1.7.x. To avoid compiler errors, import errors, syntax errors, and symbol not found errors (depending on your programming language), upgrade first to version 1.7.x of the AWS Encryption SDK. While using version 1.7.x, you can begin using the replacement elements before the original symbols are removed.

If you need to upgrade to version 2.0.x or later immediately, [consult the changelog](#) (p. 194) for your programming language, and replace the legacy symbols with the symbols the changelog recommends.

Configuration conflict: Commitment policy and algorithm suite

If you specify an algorithm suite that conflicts with your [commitment policy](#) (p. 11), the call to encrypt fails with a *Configuration conflict* error.

To avoid this type of error, don't specify an algorithm suite. By default, the AWS Encryption SDK chooses the most secure algorithm that is compatible with your commitment policy. However, if you must specify an algorithm suite, such as one without signing, be sure to choose an algorithm suite that is compatible with your commitment policy.

Commitment policy	Compatible algorithm suites
ForbidEncryptAllowDecrypt	Any algorithm suite <i>without</i> key commitment, such as: AES_256_GCM_IV12_TAG16_HKDF_SHA384_ECDSA_P384 (03 78 (p. 241)) (with signing) AES_256_GCM_IV12_TAG16_HKDF_SHA256 (01 78 (p. 241)) (without signing)
RequireEncryptAllowDecrypt RequireEncryptRequireDecrypt	Any algorithm suite <i>with</i> key commitment, such as: AES_256_GCM_HKDF_SHA512_COMMIT_KEY_ECDSA_P384 (05 78 (p. 241)) (with signing) AES_256_GCM_HKDF_SHA512_COMMIT_KEY (04 78 (p. 241)) (without signing)

If you encounter this error when you have not specified an algorithm suite, the conflicting algorithm suite might have been chosen by your [cryptographic materials manager \(p. 9\)](#) (CMM). The Default CMM won't select a conflicting algorithm suite, but a custom CMM might. For help, consult the documentation for your custom CMM.

Configuration conflict: Commitment policy and ciphertext

The `RequireEncryptRequireDecrypt` [commitment policy \(p. 11\)](#) does not permit the AWS Encryption SDK to decrypt a message that was encrypted without [key commitment \(p. 10\)](#). If you ask the AWS Encryption SDK to decrypt a message without key commitment, it returns a *Configuration conflict* error.

To avoid this error, before setting the `RequireEncryptRequireDecrypt` commitment policy, be sure that all ciphertexts encrypted without key commitment are decrypted and re-encrypted with key commitment, or handled by a different application. If you encounter this error, you can return an error for the conflicting ciphertext or change your commitment policy temporarily to `RequireEncryptAllowDecrypt`.

If you are encountering this error because you upgraded to version 2.0.x or later from a version earlier than 1.7.x, you might consider [rolling back \(p. 219\)](#) to version 1.7.x and deploying that version to all hosts before upgrading to version 2.0.x or later. For help, see [How to migrate and deploy the AWS Encryption SDK \(p. 203\)](#).

Key commitment validation failed

When you decrypt messages that are encrypted with key commitment, you might get a *Key commitment validation failed* error message. This indicates that the decrypt call failed because a data key in an [encrypted message \(p. 6\)](#) is not identical to the unique data key for the message. By validating the data key during decryption, [key commitment \(p. 10\)](#) protects you from decrypting a message that might result in more than one plaintext.

This error indicates that the encrypted message that you were trying to decrypt was not returned by the AWS Encryption SDK. It might be a manually crafted message or the result of data corruption. If you encounter this error, your application can reject the message and continue, or stop processing new messages.

Other encryption failures

Encryption can fail for multiple reasons. You cannot use an [AWS KMS discovery keyring \(p. 55\)](#) or a [master key provider in discovery mode \(p. 204\)](#) to encrypt a message.

Be sure that you specify a keyring or master key provider with wrapping keys that you have [permission to use \(p. 49\)](#) for encryption. For help with permissions on AWS KMS keys, see [Viewing a key policy](#) and [Determining access to an AWS KMS key](#) in the *AWS Key Management Service Developer Guide*.

Other decryption failures

If your attempt to decrypt an encrypted message fails, it means that the AWS Encryption SDK could not (or would not) decrypt any of the encrypted data keys in the message.

If you used a keyring or master key provider that specifies wrapping keys, the AWS Encryption SDK uses only the wrapping keys you specify. Verify that you are using the wrapping keys that you intend and that you have `kms:Decrypt` permission on at least one of the wrapping keys. If you are using AWS KMS keys, as a fallback, you can try decrypting the message with an [AWS KMS discovery keyring \(p. 55\)](#) or a [master key provider in discovery mode \(p. 204\)](#). If the operation succeeds, before returning the plaintext, verify that the key used to decrypt the message is one that you trust.

Rollback considerations

If your application is failing to encrypt or decrypt data, you can usually resolve the problem by updating the code symbols, keyrings, master key providers, or [commitment policy \(p. 11\)](#). However, in some cases, you might decide that it's best to roll back your application to a previous version of the AWS Encryption SDK.

If you must roll back, do so with caution. Versions of the AWS Encryption SDK prior to 1.7.x cannot decrypt ciphertext encrypted with [key commitment \(p. 10\)](#).

- Rolling back from version 1.7.x to a previous version of the AWS Encryption SDK is generally safe. You might have to undo changes you made to your code to use symbols and objects that are not supported in previous versions.
- Once you have begun encrypting with key commitment (setting your commitment policy to `RequireEncryptAllowDecrypt`) in version 2.0.x or later, you can roll back to version 1.7.x, but not to any earlier version. Versions of the AWS Encryption SDK prior to 1.7.x cannot decrypt ciphertext encrypted with [key commitment \(p. 10\)](#).

If you accidentally enable encrypting with key commitment before all hosts can decrypt with key commitment, it might be best to continue with the roll out rather than to roll back. If messages are transient or can be safely dropped, then you might consider a rollback with loss of messages. If a rollback is required, you might consider writing a tool that decrypts and re-encrypts all messages.

How is the AWS Encryption SDK different from the AWS SDKs?

The [AWS SDKs](#) provide libraries for interacting with Amazon Web Services (AWS), including AWS Key Management Service (AWS KMS). Some of the language implementations of the AWS Encryption SDK, such as the [AWS Encryption SDK for .NET \(p. 78\)](#), always require the AWS SDK in the same programming language. Other language implementations require the corresponding AWS SDK only when you use AWS KMS keys in your keyrings or master key providers. For details, see the topic about your programming language in [AWS Encryption SDK programming languages \(p. 68\)](#).

You can use the AWS SDKs to interact with AWS KMS, including encrypting and decrypting small amounts of data (up to 4,096 bytes with a symmetric encryption key) and generating data keys for client-side encryption. However, when you generate a data key, you must manage the entire encryption and decryption process, including encrypting your data with the data key outside of AWS KMS, safely discarding the plaintext data key, storing the encrypted data key, and then decrypting the data key and decrypting your data. The AWS Encryption SDK handles this process for you.

The AWS Encryption SDK provides a library that encrypts and decrypts data using industry standards and best practices. It generates the data key, encrypts it under the wrapping keys you specify, and returns an *encrypted message*, a portable data object that includes the encrypted data and the encrypted data keys you need to decrypt it. When it's time to decrypt, you pass in the encrypted message and at least one of the wrapping keys (optional), and the AWS Encryption SDK returns your plaintext data.

You can use AWS KMS keys as wrapping keys in the AWS Encryption SDK, but it is not required. You can use encryption keys that you generate and those from your key manager or on-premises hardware security module. You can use the AWS Encryption SDK even if you don't have an AWS account.

How is the AWS Encryption SDK different from the Amazon S3 encryption client?

The [Amazon S3 encryption client](#) in the AWS SDKs provides encryption and decryption for data that you store in Amazon Simple Storage Service (Amazon S3). These clients are tightly coupled to Amazon S3 and are intended for use only with data stored there.

The AWS Encryption SDK provides encryption and decryption for data that you can store anywhere. The AWS Encryption SDK and the Amazon S3 encryption client are not compatible because they produce ciphertexts with different data formats.

Which cryptographic algorithms are supported by the AWS Encryption SDK, and which one is the default?

The AWS Encryption SDK uses the Advanced Encryption Standard (AES) symmetric algorithm in Galois/Counter Mode (GCM), known as AES-GCM, to encrypt your data. It lets you choose from several symmetric and asymmetric algorithms to encrypt the data keys that encrypt your data.

For AES-GCM, the default algorithm suite is AES-GCM with a 256-bit key, key derivation (HKDF), [digital signatures \(p. 12\)](#), and [key commitment \(p. 10\)](#). AWS Encryption SDK also supports 192-bit, and 128-bit encryption keys and encryption algorithms without digital signatures and key commitment.

In all cases, the length of the initialization vector (IV) is 12 bytes; the length of the authentication tag is 16 bytes. By default, the SDK uses the data key as an input to the HMAC-based extract-and-expand key derivation function (HKDF) to derive the AES-GCM encryption key, and also adds an Elliptic Curve Digital Signature Algorithm (ECDSA) signature.

For information about choosing which algorithm to use, see [Supported algorithm suites \(p. 13\)](#).

For implementation details about the supported algorithms, see [Algorithms reference \(p. 241\)](#).

How is the initialization vector (IV) generated and where is it stored?

The AWS Encryption SDK uses a deterministic method to construct a different IV value for each frame. This procedure guarantees that IVs are never repeated within a message. (Prior to version 1.3.0 of the AWS Encryption SDK for Java and the AWS Encryption SDK for Python, the AWS Encryption SDK randomly generated a unique IV value for each frame.)

The IV is stored in the encrypted message that the AWS Encryption SDK returns. For more information, see the [AWS Encryption SDK message format reference \(p. 224\)](#).

How is each data key generated, encrypted, and decrypted?

The method depends on the keyring or master key provider you use.

The AWS KMS keyrings and master key providers in the AWS Encryption SDK use the AWS KMS [GenerateDataKey](#) API operation to generate each data key and encrypt it under its wrapping key. To encrypt copies of the data key under additional KMS keys, they use the AWS KMS [Encrypt](#) operation. To decrypt the data keys, they use the AWS KMS [Decrypt](#) operation. For details, see [AWS KMS keyring](#) in the AWS Encryption SDK Specification in GitHub.

Other keyrings generate the data key, encrypt, and decrypt using best practice methods for each programming language. For details, see the specification of the keyring or master key provider in the [Framework section](#) of the AWS Encryption SDK Specification in GitHub.

How do I keep track of the data keys that were used to encrypt my data?

The AWS Encryption SDK does this for you. When you encrypt data, the SDK encrypts the data key and stores the encrypted key along with the encrypted data in the [encrypted message \(p. 8\)](#) that it returns. When you decrypt data, the AWS Encryption SDK extracts the encrypted data key from the encrypted message, decrypts it, and then uses it to decrypt the data.

How does the AWS Encryption SDK store encrypted data keys with their encrypted data?

The encryption operations in the AWS Encryption SDK return an [encrypted message \(p. 8\)](#), a single data structure that contains the encrypted data and its encrypted data keys. The message format consists of at least two parts: a *header* and a *body*. The message header contains the encrypted data keys and information about how the message body is formed. The message body contains the encrypted data. If the algorithm suite includes a [digital signature \(p. 12\)](#), the message format

includes a *footer* that contains the signature. For more information, see [AWS Encryption SDK message format reference \(p. 224\)](#).

How much overhead does the AWS Encryption SDK message format add to my encrypted data?

The amount of overhead added by the AWS Encryption SDK depends on several factors, including the following:

- The size of the plaintext data
- Which of the supported algorithms is used
- Whether additional authenticated data (AAD) is provided, and the length of that AAD
- The number and type of wrapping keys or master keys
- The frame size (when [framed data \(p. 231\)](#) is used)

When you use the AWS Encryption SDK with its default configuration (one AWS KMS key as the wrapping key (or master key), no AAD, nonframed data, and an encryption algorithm with signing), the overhead is approximately 600 bytes. In general, you can reasonably assume that the AWS Encryption SDK adds overhead of 1 KB or less, not including the provided AAD. For more information, see [AWS Encryption SDK message format reference \(p. 224\)](#).

Can I use my own master key provider?

Yes. The implementation details vary depending on which of the [supported programming languages \(p. 68\)](#) you use. However, all supported languages allow you to define custom [cryptographic materials managers \(CMMs\) \(p. 9\)](#), master key providers, keyrings, master keys, and wrapping keys.

Can I encrypt data under more than one wrapping key?

Yes. You can encrypt the data key with additional wrapping keys (or master keys) to add redundancy when the key is in a different region or is unavailable for decryption.

To encrypt data under multiple wrapping keys, create a keyring or master key provider with multiple wrapping keys. When working with keyrings, you can create a [single keyring with multiple wrapping keys \(p. 50\)](#) or a [multi-keyring \(p. 64\)](#).

When you encrypt data with multiple wrapping keys, the AWS Encryption SDK uses one wrapping key to generate a plaintext data key. The data key is unique and mathematically unrelated to the wrapping key. The operation returns the plaintext data key and a copy of the data key encrypted by the wrapping key. Then the encryption method, encrypts the data key with the other wrapping keys. The resulting [encrypted message \(p. 8\)](#) includes the encrypted data and one encrypted data key for each wrapping key.

The encrypted message can be decrypted by using any one of the wrapping keys used in the encryption operation. The AWS Encryption SDK uses a wrapping key to decrypt an encrypted data key. Then, it uses the plaintext data key to decrypt the data.

Which data types can I encrypt with the AWS Encryption SDK?

Most programming language implementations of the AWS Encryption SDK can encrypt raw bytes (byte arrays), I/O streams (byte streams), and strings. The AWS Encryption SDK for .NET does not support I/O streams. We provide example code for each of the [supported programming languages \(p. 68\)](#).

How does the AWS Encryption SDK encrypt and decrypt input/output (I/O) streams?

The AWS Encryption SDK creates an encrypting or decrypting stream that wraps an underlying I/O stream. The encrypting or decrypting stream performs a cryptographic operation on a read or write call. For example, it can read plaintext data on the underlying stream and encrypt it before returning the result. Or it can read ciphertext from an underlying stream and decrypt it before returning the result. We provide example code for encrypting and decrypting streams for each of the [supported programming languages \(p. 68\)](#) that supports streaming.

The AWS Encryption SDK for .NET does not support I/O streams.

AWS Encryption SDK reference

The information on this page is a reference for building your own encryption library that is compatible with the AWS Encryption SDK. If you are not building your own compatible encryption library, you likely do not need this information.

To use the AWS Encryption SDK in one of the supported programming languages, see [Programming languages \(p. 68\)](#).

For the specification that defines the elements of a proper AWS Encryption SDK implementation, see the [AWS Encryption SDK Specification](#) in GitHub.

The AWS Encryption SDK uses the [supported algorithms \(p. 13\)](#) to return a single data structure or *message* that contains encrypted data and the corresponding encrypted data keys. The following topics explain the algorithms and the data structure. Use this information to build libraries that can read and write ciphertexts that are compatible with this SDK.

Topics

- [AWS Encryption SDK message format reference \(p. 224\)](#)
- [AWS Encryption SDK message format examples \(p. 233\)](#)
- [Body additional authenticated data \(AAD\) reference for the AWS Encryption SDK \(p. 240\)](#)
- [AWS Encryption SDK algorithms reference \(p. 241\)](#)
- [AWS Encryption SDK initialization vector reference \(p. 244\)](#)

AWS Encryption SDK message format reference

The information on this page is a reference for building your own encryption library that is compatible with the AWS Encryption SDK. If you are not building your own compatible encryption library, you likely do not need this information.

To use the AWS Encryption SDK in one of the supported programming languages, see [Programming languages \(p. 68\)](#).

For the specification that defines the elements of a proper AWS Encryption SDK implementation, see the [AWS Encryption SDK Specification](#) in GitHub.

The encryption operations in the AWS Encryption SDK return a single data structure or [encrypted message \(p. 8\)](#) that contains the encrypted data (ciphertext) and all encrypted data keys. To understand this data structure, or to build libraries that read and write it, you need to understand the message format.

The message format consists of at least two parts: a *header* and a *body*. In some cases, the message format consists of a third part, a *footer*. The message format defines an ordered sequence of bytes in network byte order, also called big-endian format. The message format begins with the header, followed by the body, followed by the footer (when there is one).

The [algorithms suites \(p. 241\)](#) supported by the AWS Encryption SDK use one of two message format versions. Algorithm suites without [key commitment \(p. 10\)](#) use message format version 1. Algorithm suites with key commitment use message format version 2.

Topics

- [Header structure \(p. 225\)](#)
- [Body structure \(p. 230\)](#)
- [Footer structure \(p. 233\)](#)

Header structure

The message header contains the encrypted data key and information about how the message body is formed. The following table describes the fields that form the header in message format versions 1 and 2. The bytes are appended in the order shown.

The **Not present** value indicates that the field doesn't exist in that version of the message format. **Bold text** indicates values that are different in each version.

Note

You might need to scroll horizontally or vertically to see all of the data in this table.

Header Structure

Field	Message format version 1 Length (bytes)	Message format version 2 Length (bytes)
Version (p. 226)	1	1
Type (p. 226)	1	Not present
Algorithm ID (p. 226)	2	2
Message ID (p. 226)	16	32
AAD Length (p. 226)	2 When the encryption context (p. 8) is empty, the value of the 2-byte AAD Length field is 0.	2 When the encryption context (p. 8) is empty, the value of the 2-byte AAD Length field is 0.
AAD (p. 226)	Variable. The length of this field appears in the previous 2 bytes (AAD Length field). When the encryption context (p. 8) is empty, there is no AAD field in the header.	Variable. The length of this field appears in the previous 2 bytes (AAD Length field). When the encryption context (p. 8) is empty, there is no AAD field in the header.
Encrypted Data Key Count (p. 227)	2	2
Encrypted Data Key(s) (p. 227)	Variable. Determined by the number of encrypted data keys and the length of each.	Variable. Determined by the number of encrypted data keys and the length of each.
Content Type (p. 228)	1	1

Field	Message format version 1 Length (bytes)	Message format version 2 Length (bytes)
Reserved (p. 229)	4	Not present
IV Length (p. 229)	1	Not present
Frame Length (p. 229)	4	4
Algorithm Suite Data (p. 229)	Not present	Variable. Determined by the algorithm (p. 241) that generated the message.
Header Authentication (p. 229)	Variable. Determined by the algorithm (p. 241) that generated the message.	Variable. Determined by the algorithm (p. 241) that generated the message.

Version

The version of this message format. The version is either 1 or 2 encoded as the byte 01 or 02 in hexadecimal notation

Type

The type of this message format. The type indicates the kind of structure. The only supported type is described as *customer authenticated encrypted data*. Its type value is 128, encoded as byte 80 in hexadecimal notation.

This field is not present in message format version 2.

Algorithm ID

An identifier for the algorithm used. It is a 2-byte value interpreted as a 16-bit unsigned integer. For more information about the algorithms, see [AWS Encryption SDK algorithms reference \(p. 241\)](#).

Message ID

A randomly generated value that identifies the message. The Message ID:

- Uniquely identifies the encrypted message.
- Weakly binds the message header to the message body.
- Provides a mechanism to securely reuse a data key with multiple encrypted messages.
- Protects against accidental reuse of a data key or the wearing out of keys in the AWS Encryption SDK.

This value is 128 bits in message format version 1 and 256 bits in version 2.

AAD Length

The length of the additional authenticated data (AAD). It is a 2-byte value interpreted as a 16-bit unsigned integer that specifies the number of bytes that contain the AAD.

When the [encryption context \(p. 8\)](#) is empty, the value of the AAD Length field is 0.

AAD

The additional authenticated data. The AAD is an encoding of the [encryption context \(p. 8\)](#), an array of key-value pairs where each key and value is a string of UTF-8 encoded characters. The encryption context is converted to a sequence of bytes and used for the AAD value. When the encryption context is empty, there is no AAD field in the header.

When the [algorithms with signing \(p. 241\)](#) are used, the encryption context must contain the key-value pair `{ 'aws-crypto-public-key', Qtxt }`. Qtxt represents the elliptic curve point Q compressed according to [SEC 1 version 2.0](#) and then base64-encoded. The encryption context can contain additional values, but the maximum length of the constructed AAD is $2^{16} - 1$ bytes.

The following table describes the fields that form the AAD. Key-value pairs are sorted, by key, in ascending order according to UTF-8 character code. The bytes are appended in the order shown.

AAD Structure

Field	Length (bytes)
Key-Value Pair Count (p. 227)	2
Key Length (p. 227)	2
Key (p. 227)	Variable. Equal to the value specified in the previous 2 bytes (Key Length).
Value Length (p. 227)	2
Value (p. 227)	Variable. Equal to the value specified in the previous 2 bytes (Value Length).

Key-Value Pair Count

The number of key-value pairs in the AAD. It is a 2-byte value interpreted as a 16-bit unsigned integer that specifies the number of key-value pairs in the AAD. The maximum number of key-value pairs in the AAD is $2^{16} - 1$.

When there is no encryption context or the encryption context is empty, this field is not present in the AAD structure.

Key Length

The length of the key for the key-value pair. It is a 2-byte value interpreted as a 16-bit unsigned integer that specifies the number of bytes that contain the key.

Key

The key for the key-value pair. It is a sequence of UTF-8 encoded bytes.

Value Length

The length of the value for the key-value pair. It is a 2-byte value interpreted as a 16-bit unsigned integer that specifies the number of bytes that contain the value.

Value

The value for the key-value pair. It is a sequence of UTF-8 encoded bytes.

Encrypted Data Key Count

The number of encrypted data keys. It is a 2-byte value interpreted as a 16-bit unsigned integer that specifies the number of encrypted data keys. The maximum number of encrypted data keys in each message is 65,535 ($2^{16} - 1$).

Encrypted Data Key(s)

A sequence of encrypted data keys. The length of the sequence is determined by the number of encrypted data keys and the length of each. The sequence contains at least one encrypted data key.

The following table describes the fields that form each encrypted data key. The bytes are appended in the order shown.

Encrypted Data Key Structure

Field	Length (bytes)
Key Provider ID Length (p. 228)	2
Key Provider ID (p. 228)	Variable. Equal to the value specified in the previous 2 bytes (Key Provider ID Length).
Key Provider Information Length (p. 228)	2
Key Provider Information (p. 228)	Variable. Equal to the value specified in the previous 2 bytes (Key Provider Information Length).
Encrypted Data Key Length (p. 228)	2
Encrypted Data Key (p. 228)	Variable. Equal to the value specified in the previous 2 bytes (Encrypted Data Key Length).

Key Provider ID Length

The length of the key provider identifier. It is a 2-byte value interpreted as a 16-bit unsigned integer that specifies the number of bytes that contain the key provider ID.

Key Provider ID

The key provider identifier. It is used to indicate the provider of the encrypted data key and intended to be extensible.

Key Provider Information Length

The length of the key provider information. It is a 2-byte value interpreted as a 16-bit unsigned integer that specifies the number of bytes that contain the key provider information.

Key Provider Information

The key provider information. It is determined by the key provider.

When AWS KMS is the master key provider or you are using an AWS KMS keyring, this value contains the Amazon Resource Name (ARN) of the AWS KMS key.

Encrypted Data Key Length

The length of the encrypted data key. It is a 2-byte value interpreted as a 16-bit unsigned integer that specifies the number of bytes that contain the encrypted data key.

Encrypted Data Key

The encrypted data key. It is the data encryption key encrypted by the key provider.

Content Type

The type of encrypted data, either nonframed or framed.

Note

Whenever possible, use framed data. The AWS Encryption SDK supports nonframed data only for legacy use. Some language implementations of the AWS Encryption SDK can still generate nonframed ciphertext. All supported language implementations can decrypt framed and nonframed ciphertext.

Framed data is divided into equal-length parts; each part is encrypted separately. Framed content is type 2, encoded as the byte 02 in hexadecimal notation.

Nonframed data is not divided; it is a single encrypted blob. Non-framed content is type 1, encoded as the byte 01 in hexadecimal notation.

Reserved

A reserved sequence of 4 bytes. This value must be 0. It is encoded as the bytes 00 00 00 00 in hexadecimal notation (that is, a 4-byte sequence of a 32-bit integer value equal to 0).

This field is not present in message format version 2.

IV Length

The length of the initialization vector (IV). It is a 1-byte value interpreted as an 8-bit unsigned integer that specifies the number of bytes that contain the IV. This value is determined by the IV bytes value of the [algorithm \(p. 241\)](#) that generated the message.

This field is not present in message format version 2, which only supports algorithm suites that use deterministic IV values in the message header.

Frame Length

The length of each frame of framed data. It is a 4-byte value interpreted as a 32-bit unsigned integer that specifies the number of bytes in each frame. When the data is nonframed, that is, when the value of the `Content Type` field is 1, this value must be 0.

Note

Whenever possible, use framed data. The AWS Encryption SDK supports nonframed data only for legacy use. Some language implementations of the AWS Encryption SDK can still generate nonframed ciphertext. All supported language implementations can decrypt framed and nonframed ciphertext.

Algorithm Suite Data

Supplementary data needed by the [algorithm \(p. 241\)](#) that generated the message. The length and contents are determined by the algorithm. Its length might be 0.

This field is not present in message format version 1.

Header Authentication

The header authentication is determined by the [algorithm \(p. 241\)](#) that generated the message. The header authentication is calculated over the entire header. It consists of an IV and an authentication tag. The bytes are appended in the order shown.

Header Authentication Structure

Field	Length in version 1.0 (bytes)	Length in version 2.0 (bytes)
IV (p. 229)	Variable. Determined by the IV bytes value of the algorithm (p. 241) that generated the message.	N/A
Authentication Tag (p. 230)	Variable. Determined by the authentication tag bytes value of the algorithm (p. 241) that generated the message.	Variable. Determined by the authentication tag bytes value of the algorithm (p. 241) that generated the message.

IV

The initialization vector (IV) used to calculate the header authentication tag.

This field is not present in the header of message format version 2. Message format version 2 only supports algorithm suites that use deterministic IV values in the message header.

Authentication Tag

The authentication value for the header. It is used to authenticate the entire contents of the header.

Body structure

The message body contains the encrypted data, called the *ciphertext*. The structure of the body depends on the content type (nonframed or framed). The following sections describe the format of the message body for each content type. The message body structure is the same in message format versions 1 and 2.

Topics

- [Non-framed data \(p. 230\)](#)
- [Framed data \(p. 231\)](#)

Non-framed data

Non-framed data is encrypted in a single blob with a unique IV and [body AAD \(p. 240\)](#).

Note

Whenever possible, use framed data. The AWS Encryption SDK supports nonframed data only for legacy use. Some language implementations of the AWS Encryption SDK can still generate nonframed ciphertext. All supported language implementations can decrypt framed and nonframed ciphertext.

The following table describes the fields that form nonframed data. The bytes are appended in the order shown.

Non-Framed Body Structure

Field	Length, in bytes
IV (p. 230)	Variable. Equal to the value specified in the IV Length (p. 229) byte of the header.
Encrypted Content Length (p. 230)	8
Encrypted Content (p. 231)	Variable. Equal to the value specified in the previous 8 bytes (Encrypted Content Length).
Authentication Tag (p. 231)	Variable. Determined by the algorithm implementation (p. 241) used.

IV

The initialization vector (IV) to use with the [encryption algorithm \(p. 241\)](#).

Encrypted Content Length

The length of the encrypted content, or *ciphertext*. It is an 8-byte value interpreted as a 64-bit unsigned integer that specifies the number of bytes that contain the encrypted content.

Technically, the maximum allowed value is $2^{63} - 1$, or 8 exbibytes (8 EiB). However, in practice the maximum value is $2^{36} - 32$, or 64 gibibytes (64 GiB), due to restrictions imposed by the [implemented algorithms \(p. 241\)](#).

Note

The Java implementation of this SDK further restricts this value to $2^{31} - 1$, or 2 gibibytes (2 GiB), due to restrictions in the language.

Encrypted Content

The encrypted content (ciphertext) as returned by the [encryption algorithm](#) (p. 241).

Authentication Tag

The authentication value for the body. It is used to authenticate the message body.

Framed data

In framed data, the plaintext data is divided into equal-length parts called *frames*. The AWS Encryption SDK encrypts each frame separately with a unique IV and [body AAD](#) (p. 240).

Note

Whenever possible, use framed data. The AWS Encryption SDK supports nonframed data only for legacy use. Some language implementations of the AWS Encryption SDK can still generate nonframed ciphertext. All supported language implementations can decrypt framed and nonframed ciphertext.

The [frame length](#) (p. 229), which is the length of the [encrypted content](#) (p. 232) in the frame, can be different for each message. The maximum number of bytes in a frame is $2^{32} - 1$. The maximum number of frames in a message is $2^{32} - 1$.

There are two types of frames: *regular* and *final*. Every message must consist of or include a final frame.

All regular frames in a message have the same frame length. The final frame can have a different frame length.

The composition of frames in framed data varies with the length of the encrypted content.

- **Equal to the frame length** — When the encrypted content length is the same as the frame length of the regular frames, the message can consist of a regular frame that contains the data, followed by a final frame of zero (0) length. Or, the message can consist only of a final frame that contains the data. In this case, the final frame has the same frame length as the regular frames.
- **Multiple of the frame length** — When the encrypted content length is an exact multiple of the frame length of the regular frames, the message can end in a regular frame that contains the data, followed by a final frame of zero (0) length. Or, the message can end in a final frame that contains the data. In this case, the final frame has the same frame length as the regular frames.
- **Not a multiple of the frame length** — When the encrypted content length is not an exact multiple of the frame length of the regular frames, the final frame contains the remaining data. The frame length of the final frame is less than the frame length of the regular frames.
- **Less than the frame length** — When the encrypted content length is less than the frame length of the regular frames, the message consists of a final frame that contains all of the data. The frame length of the final frame is less than the frame length of the regular frames.

The following tables describe the fields that form the frames. The bytes are appended in the order shown.

Framed Body Structure, Regular Frame

Field	Length, in bytes
Sequence Number (p. 232)	4

Field	Length, in bytes
IV (p. 232)	Variable. Equal to the value specified in the IV Length (p. 229) byte of the header.
Encrypted Content (p. 232)	Variable. Equal to the value specified in the Frame Length (p. 229) of the header.
Authentication Tag (p. 232)	Variable. Determined by the algorithm used, as specified in the Algorithm ID (p. 226) of the header.

Sequence Number

The frame sequence number. It is an incremental counter number for the frame. It is a 4-byte value interpreted as a 32-bit unsigned integer.

Framed data must start at sequence number 1. Subsequent frames must be in order and must contain an increment of 1 of the previous frame. Otherwise, the decryption process stops and reports an error.

IV

The initialization vector (IV) for the frame. The SDK uses a deterministic method to construct a different IV for each frame in the message. Its length is specified by the [algorithm suite \(p. 241\)](#) used.

Encrypted Content

The encrypted content (ciphertext) for the frame, as returned by the [encryption algorithm \(p. 241\)](#).

Authentication Tag

The authentication value for the frame. It is used to authenticate the entire frame.

Framed Body Structure, Final Frame

Field	Length, in bytes
Sequence Number End (p. 232)	4
Sequence Number (p. 233)	4
IV (p. 233)	Variable. Equal to the value specified in the IV Length (p. 229) byte of the header.
Encrypted Content Length (p. 233)	4
Encrypted Content (p. 233)	Variable. Equal to the value specified in the previous 4 bytes (Encrypted Content Length).
Authentication Tag (p. 233)	Variable. Determined by the algorithm used, as specified in the Algorithm ID (p. 226) of the header.

Sequence Number End

An indicator for the final frame. The value is encoded as the 4 bytes `FF FF FF FF` in hexadecimal notation.

Sequence Number

The frame sequence number. It is an incremental counter number for the frame. It is a 4-byte value interpreted as a 32-bit unsigned integer.

Framed data must start at sequence number 1. Subsequent frames must be in order and must contain an increment of 1 of the previous frame. Otherwise, the decryption process stops and reports an error.

IV

The initialization vector (IV) for the frame. The SDK uses a deterministic method to construct a different IV for each frame in the message. The length of the IV length is specified by the [algorithm suite](#) (p. 241).

Encrypted Content Length

The length of the encrypted content. It is a 4-byte value interpreted as a 32-bit unsigned integer that specifies the number of bytes that contain the encrypted content for the frame.

Encrypted Content

The encrypted content (ciphertext) for the frame, as returned by the [encryption algorithm](#) (p. 241).

Authentication Tag

The authentication value for the frame. It is used to authenticate the entire frame.

Footer structure

When the [algorithms with signing](#) (p. 241) are used, the message format contains a footer. The message footer contains a [digital signature](#) (p. 12) calculated over the message header and body. The following table describes the fields that form the footer. The bytes are appended in the order shown. The message footer structure is the same in message format versions 1 and 2.

Footer Structure

Field	Length, in bytes
Signature Length (p. 233)	2
Signature (p. 233)	Variable. Equal to the value specified in the previous 2 bytes (Signature Length).

Signature Length

The length of the signature. It is a 2-byte value interpreted as a 16-bit unsigned integer that specifies the number of bytes that contain the signature.

Signature

The signature.

AWS Encryption SDK message format examples

The information on this page is a reference for building your own encryption library that is compatible with the AWS Encryption SDK. If you are not building your own compatible encryption library, you likely do not need this information.

To use the AWS Encryption SDK in one of the supported programming languages, see [Programming languages](#) (p. 68).

For the specification that defines the elements of a proper AWS Encryption SDK implementation, see the [AWS Encryption SDK Specification](#) in GitHub.

The following topics show examples of the AWS Encryption SDK message format. Each example shows the raw bytes, in hexadecimal notation, followed by a description of what those bytes represent.

Topics

- [Framed data \(message format version 1\)](#) (p. 234)
- [Framed data \(message format version 2\)](#) (p. 236)
- [Non-framed data \(message format version 1\)](#) (p. 238)

Framed data (message format version 1)

The following example shows the message format for framed data in [message format version 1](#) (p. 224).

```
+-----+
| Header |
+-----+
01                                     Version (1.0)
80                                     Type (128, customer authenticated encrypted
    data)
0378                                  Algorithm ID (see Algorithms reference)
6E7C0FBD 4DF4A999 717C22A2 DDFE1A27  Message ID (random 128-bit value)
008E                                  AAD Length (142)

Non-framed data (message format version 1)

The following example shows the message format for nonframed data.

Note

Whenever possible, use framed data. The AWS Encryption SDK supports nonframed data only for legacy use. Some language implementations of the AWS Encryption SDK can still generate nonframed ciphertext. All supported language implementations can decrypt framed and nonframed ciphertext.

Signature

Body additional authenticated data (AAD) reference for the AWS Encryption SDK

The information on this page is a reference for building your own encryption library that is compatible with the AWS Encryption SDK. If you are not building your own compatible encryption library, you likely do not need this information.

To use the AWS Encryption SDK in one of the supported programming languages, see [Programming languages \(p. 68\)](#).

For the specification that defines the elements of a proper AWS Encryption SDK implementation, see the [AWS Encryption SDK Specification](#) in GitHub.

You must provide additional authenticated data (AAD) to the [AES-GCM algorithm \(p. 241\)](#) for each cryptographic operation. This is true for both framed and nonframed [body data \(p. 230\)](#). For more information about AAD and how it is used in Galois/Counter Mode (GCM), see [Recommendations for Block Cipher Modes of Operations: Galois/Counter Mode \(GCM\) and GMAC](#).

The following table describes the fields that form the body AAD. The bytes are appended in the order shown.

Body AAD Structure

Field	Length, in bytes
Message ID (p. 241)	16
Body AAD Content (p. 241)	Variable. See Body AAD Content in the following list.
Sequence Number (p. 241)	4
Content Length (p. 241)	8

Message ID

The same [Message ID \(p. 226\)](#) value set in the message header.

Body AAD Content

A UTF-8 encoded value determined by the type of body data used.

For [nonframed data \(p. 230\)](#), use the value `AWSKMSEncryptionClient Single Block`.

For regular frames in [framed data \(p. 231\)](#), use the value `AWSKMSEncryptionClient Frame`.

For the final frame in [framed data \(p. 231\)](#), use the value `AWSKMSEncryptionClient Final Frame`.

Sequence Number

A 4-byte value interpreted as a 32-bit unsigned integer.

For [framed data \(p. 231\)](#), this is the frame sequence number.

For [nonframed data \(p. 230\)](#), use the value 1, encoded as the 4 bytes `00 00 00 01` in hexadecimal notation.

Content Length

The length, in bytes, of the plaintext data provided to the algorithm for encryption. It is an 8-byte value interpreted as a 64-bit unsigned integer.

AWS Encryption SDK algorithms reference

The information on this page is a reference for building your own encryption library that is compatible with the AWS Encryption SDK. If you are not building your own compatible encryption library, you likely do not need this information.

To use the AWS Encryption SDK in one of the supported programming languages, see [Programming languages \(p. 68\)](#).

For the specification that defines the elements of a proper AWS Encryption SDK implementation, see the [AWS Encryption SDK Specification](#) in GitHub.

If you are building your own library that can read and write ciphertexts that are compatible with the AWS Encryption SDK, you'll need to understand how the AWS Encryption SDK implements the supported algorithm suites to encrypt raw data.

The AWS Encryption SDK supports the following algorithm suites. All AES-GCM algorithm suites have a 12-byte [initialization vector](#) (p. 244) and a 16-byte AES-GCM authentication tag. The default algorithm suite varies with the AWS Encryption SDK version and the selected key commitment policy. For details, see [Commitment policy and algorithm suite](#) (p. 217).

AWS Encryption SDK Algorithm Suites

Algorithm ID	Message format version	Encryption algorithm	Data key length (bits)	Key derivation algorithm	Signature algorithm	Key commitment algorithm	Algorithm suite data length (bytes)
05 78	0x02	AES-GCM	256	HKDF with SHA-512	ECDSA with P-384 and SHA-384	HKDF with SHA-512	32 (key commitment)
04 78	0x02	AES-GCM	256	HKDF with SHA-512	None	HKDF with SHA-512	32 (key commitment)
03 78	0x01	AES-GCM	256	HKDF with SHA-384	ECDSA with P-384 and SHA-384	None	N/A
03 46	0x01	AES-GCM	192	HKDF with SHA-384	ECDSA with P-384 and SHA-384	None	N/A
02 14	0x01	AES-GCM	128	HKDF with SHA-256	ECDSA with P-256 and SHA-256	None	N/A
01 78	0x01	AES-GCM	256	HKDF with SHA-256	None	None	N/A
01 46	0x01	AES-GCM	192	HKDF with SHA-256	None	None	N/A
01 14	0x01	AES-GCM	128	HKDF with SHA-256	None	None	N/A
00 78	0x01	AES-GCM	256	None	None	None	N/A
00 46	0x01	AES-GCM	192	None	None	None	N/A
00 14	0x01	AES-GCM	128	None	None	None	N/A

Algorithm ID

A 2-byte hexadecimal value that uniquely identifies an algorithm implementation. This value is stored in the [message header](#) (p. 225) of the ciphertext.

Message format version

The version of the message format. Algorithm suites with key commitment use message format version 2 (0x02). Algorithm suites without key commitment use message format version 1 (0x01).

Algorithm suite data length

The length in bytes of data specific to the algorithm suite. This field is supported only in message format version 2 (0x02). In message format version 2 (0x02), this data appears in the `Algorithm suite data` field of the message header. Algorithm suites that support [key commitment \(p. 10\)](#) use 32 bytes for the key commitment string. For more information, see **Key commitment algorithm** in this list.

Data key length

The length of the [data key \(p. 6\)](#) in bits. The AWS Encryption SDK supports 256-bit, 192-bit, and 128-bit keys. The data key is generated by a [keyring \(p. 7\)](#) or master key.

In some implementations, this data key is used as input to an HMAC-based extract-and-expand key derivation function (HKDF). The output of the HKDF is used as the data encryption key in the encryption algorithm. For more information, see **Key derivation algorithm** in this list.

Encryption algorithm

The name and mode of the encryption algorithm used. Algorithm suites in the AWS Encryption SDK use the Advanced Encryption Standard (AES) encryption algorithm with Galois/Counter Mode (GCM).

Key commitment algorithm

The algorithm used to calculate the key commitment string. The output is stored in the `Algorithm suite data` field of the message header and is used to validate the data key for key commitment.

For a technical explanation of adding key commitment to an algorithm suite, see [Key Committing AEADs](#) in Cryptology ePrint Archive.

Key derivation algorithm

The HMAC-based extract-and-expand key derivation function (HKDF) used to derive the data encryption key. The AWS Encryption SDK uses the HKDF defined in [RFC 5869](#).

Algorithm suites without key commitment (algorithm ID 01xx – 03xx)

- The hash function used is either SHA-384 or SHA-256, depending on the algorithm suite.
- For the extract step:
 - No salt is used. Per the RFC, the salt is set to a string of zeros. The string length is equal to the length of the hash function output, which is 48 bytes for SHA-384 and 32 bytes for SHA-256.
 - The input keying material is the data key from the keyring or master key provider.
- For the expand step:
 - The input pseudorandom key is the output from the extract step.
 - The input info is a concatenation of the algorithm ID and message ID (in that order).
 - The length of the output keying material is the **Data key length**. This output is used as the data encryption key in the encryption algorithm.

Algorithm suites with key commitment (algorithm ID 04xx and 05xx)

- The hash function used is SHA-512.
- For the extract step:
 - The salt is a 256-bit cryptographic random value. In [message format version 2 \(p. 224\)](#) (0x02), this value is stored in the `MessageID` field.
 - The initial keying material is the data key from the keyring or master key provider.
- For the expand step:

- The input pseudorandom key is the output from the extract step.
- The key label is the UTF-8-encoded bytes of the `DERIVEKEY` string in big endian byte order.
- The input info is a concatenation of the algorithm ID and the key label (in that order).
- The length of the output keying material is the **Data key length**. This output is used as the data encryption key in the encryption algorithm.

Message format version

The version of the message format used with the algorithm suite. For details, see [Message format reference \(p. 224\)](#).

Signature algorithm

The signature algorithm that is used to generate a [digital signature \(p. 12\)](#) over the ciphertext header and body. The AWS Encryption SDK uses the Elliptic Curve Digital Signature Algorithm (ECDSA) with the following specifics:

- The elliptic curve used is either the P-384 or P-256 curve, as specified by the algorithm ID. These curves are defined in [Digital Signature Standard \(DSS\) \(FIPS PUB 186-4\)](#).
- The hash function used is SHA-384 (with the P-384 curve) or SHA-256 (with the P-256 curve).

AWS Encryption SDK initialization vector reference

The information on this page is a reference for building your own encryption library that is compatible with the AWS Encryption SDK. If you are not building your own compatible encryption library, you likely do not need this information.

To use the AWS Encryption SDK in one of the supported programming languages, see [Programming languages \(p. 68\)](#).

For the specification that defines the elements of a proper AWS Encryption SDK implementation, see the [AWS Encryption SDK Specification](#) in GitHub.

The AWS Encryption SDK supplies the [initialization vectors \(IVs\)](#) that are required by all supported [algorithm suites \(p. 241\)](#). The SDK uses frame sequence numbers to construct an IV so that no two frames in the same message can have the same IV.

Each 96-bit (12-byte) IV is constructed from two big-endian byte arrays concatenated in the following order:

- 64 bits: 0 (reserved for future use)
- 32 bits: Frame sequence number. For the header authentication tag, this value is all zeroes.

Before the introduction of [data key caching \(p. 152\)](#), the AWS Encryption SDK always used a new data key to encrypt each message, and it generated all IVs randomly. Randomly generated IVs were cryptographically safe because data keys were never reused. When the SDK introduced data key caching, which intentionally reuses data keys, we changed the way the SDK generates IVs.

Using deterministic IVs that cannot repeat within a message significantly increases the number of invocations that can safely be executed under a single data key. In addition, data keys that are cached always use an algorithm suite with a [key derivation function](#). Using a deterministic IV with a pseudo-random key derivation function to derive encryption keys from a data key allows the AWS Encryption SDK to encrypt 2^{32} messages without exceeding cryptographic bounds.

Document history for the AWS Encryption SDK Developer Guide

This topic describes significant updates to the *AWS Encryption SDK Developer Guide*.

Topics

- [Recent updates \(p. 245\)](#)
- [Earlier updates \(p. 246\)](#)

Recent updates

The following table describes significant changes to this documentation since November 2017. In addition to major changes listed here, we also update the documentation frequently to improve the descriptions and examples, and to address the feedback that you send to us. To be notified about significant changes, subscribe to the RSS feed.

update-history-change	update-history-description	update-history-date
General availability	Introducing support for the AWS Encryption SDK for .NET.	May 17, 2022
Documentation change	Replace the AWS Key Management Service term <i>customer master key (CMK)</i> with <i>AWS KMS key</i> and <i>KMS key</i> .	August 30, 2021
General availability	Added support for AWS Key Management Service.(AWS KMS) multi-Region keys. Multi-Region keys are AWS KMS keys in different AWS Regions that can be used interchangeably because they have the same key ID and key material.	June 8, 2021
General availability	Added and updated documentation about the improved message decryption process.	May 11, 2021
General availability	Added and updated documentation for the general availability release of AWS Encryption CLI version 1.8.x to replace AWS Encryption CLI version 1.7.x, and AWS Encryption CLI 2.1.x to replace AWS Encryption CLI 2.0.x.	October 27, 2020

General availability	Added and updated documentation for the general availability release of the AWS Encryption SDK versions 1.7.x and 2.0.x, including a best practices guide , a migration guide , updated programming language topics , an updated algorithm suites reference , an updated message format reference , and a new message format example .	September 24, 2020
General availability	Added and updated documentation for the general availability release of the AWS Encryption SDK for JavaScript .	October 1, 2019
Preview release	Added and updated documentation of the public beta release of the AWS Encryption SDK for JavaScript .	June 21, 2019
General availability	Added and updated documentation for the general availability release of the AWS Encryption SDK for C .	May 16, 2019
Preview release	Added documentation of the preview release of the AWS Encryption SDK for C .	February 5, 2019
New release	Added documentation of the command line interface for the AWS Encryption SDK.	November 20, 2017

Earlier updates

The following table describes significant changes to the *AWS Encryption SDK Developer Guide* before November 2017.

Change	Description	Date
New release	<p>Added the Data key caching (p. 152) chapter for the new feature.</p> <p>Added the the section called "Initialization vector reference" (p. 244) topic that explains that the SDK changed from generating random IVs to constructing deterministic IVs.</p> <p>Added the the section called "Concepts" (p. 4) topic to</p>	July 31, 2017

Change	Description	Date
	explain concepts, including the new cryptographic materials manager.	
Update	Expanded the Message format reference (p. 224) documentation into a new AWS Encryption SDK reference (p. 224) section. Added a section about the AWS Encryption SDK Supported algorithm suites (p. 13) .	March 21, 2017
New release	The AWS Encryption SDK now supports the Python (p. 103) programming language, in addition to Java (p. 85) .	March 21, 2017
Initial release	Initial release of the AWS Encryption SDK and this documentation.	March 22, 2016
